## 1. Executive Summary

The Survey Research Unit (SRU) at the University of North Carolina at Chapel Hill and the Los Angeles Homeless Services Authority (LAHSA) collaborated in the design, implementation and analysis of the 2011 Greater Los Angeles Homeless Count (HC11). The SRU's responsibilities were to provide methodology and process direction, to design and select all required samples, to develop estimation strategies, and to produce all estimates. Additionally, the SRU conducted telephone surveys in households residing within the Los Angeles Continuum of Care (CoC) to look for the hidden homeless<sup>1</sup>. LAHSA's roles included managing all other data collection tasks, including conducting the street and shelter counts, establishing the contents of survey questions and forms, administering the demographic survey, compiling the estimates for presentation, and conducting a separate youth count.

Sampling played an important role in HC11 and was conducted jointly by LAHSA and the SRU between October 2010 and May 2011. The overarching goal of HC11 was to provide the homeless counts LAHSA needs to plan and maintain its service programs. A selection of samples was needed for this study since, other than for overall homeless counts of the sheltered homeless, complete enumerations to obtain the needed counts were not practical. The geographic area targeted for all of these samples was the Los Angeles Continuum of Care, which defines the coverage area of the homeless services it provides.<sup>2</sup> In all, three sets of counts or rates of homelessness required some type of sampling for estimation. They included: (i) count of street homeless from a sample of well-defined geographic areas with the CoC between January 25 and 27, 2011, (ii) rates of various categories of homelessness from information gleaned from the HC11 Demographic Survey, and (iii) counts of hidden homeless based on a telephone survey of households in the CoC. Standard methods of probability sampling were used in choosing all of these samples as described more fully below.

Measures of the statistical quality were produced in the form of estimated standard errors wherever possible. HC11 street estimates, for example, were produced in SUDAAN (Version 10, RTI International), a statistical software package that is used to analyze data from complex sample surveys. SUDAAN not only produces point estimates from survey data, but also enables us to compute the corresponding standard errors of these estimates using an appropriate survey design. Estimates at the CoC and Service Planning Area (SPA) level were the most precise since the sample was designed to include this capacity. However, many estimates at the supervisorial district (SD) or city council district (CD) proved to be unstable and should be used with caution because the relative standard error (RSE) for many of these estimates are greater than 30%.

---

<sup>1</sup> Hidden homeless persons are those who live among, but not directly with, the residential population of a community. For example, a person who lives in the garage or on the back porch of household would be considered a hidden homeless person linked to that household.

<sup>2</sup> The Los Angeles Homeless Services Authority (LAHSA) Community of Care (CoC) includes all of Los Angeles county except for the cities of Pasadena, Glendale and Long Beach.

## 2. Background and Overview

As in the past, statistical sampling played an important role in studying homeless persons served by the Los Angeles Homeless Services Authority (LAHSA) within its Continuum of Care (CoC) in 2011. The Survey Research Unit (SRU) at UNC-CH once again partnered with LAHSA in conducting the latter's Homeless Count for 2011 (referred to simply as "HC11" in the sequel). LAHSA's roles were to establish the information goals and to organize and manage all HC11 data field data gathering, except for a telephone survey of homeless persons living on residential property (i.e., the "hidden homeless") in the CoC. The SRU's complementary responsibilities were to provide all needed technical assistance in conjunction with statistical sampling, to collect telephone survey data on hidden homelessness, and to produce findings for LAHSA to report from the data collected in all HC11 sample survey components (see below). HC11 activities at the SRU were led by Dr. Robert Agans, whose specific roles were overall project management, questionnaire design and testing, and generating analysis findings. Dr. Kalsbeek's role was to assist Dr. Agans by: (i) developing the design for all required statistical samples, (ii) directing sample selection for all of the samples designed (but excluding selection of the survey sample of street and shelter homeless persons to assess demographic characteristics of homeless in the CoC), (iii) developing an alternative estimator of the number of hidden homeless from the telephone survey, and (iv) overseeing the computation of sampling weights for all HC11 samples.

Based on the final draft of the proposed study timeline in the Statement of Work, the period of performance for HC11 activities was expected to be from October 1, 2010 through May 31, 2011, with sample design and selection activities occurring between October 1, 2010 and December 31, 2010, and pre-analysis sample weights computation happening between January 1, 2011 and March 31, 2011. The actual timeline for sample design and selection at the SRU was from October 1, 2010 through March 11, 2011, and computing weights for HC11 samples was done between April 20, 2011 and May 13, 2011.

The overarching goal of HC11 was to produce the best possible estimates of homeless counts for the CoC as well as for numerous geographic and other defined subgroups of the CoC.<sup>3</sup> The target area of all HC11 samples was the CoC, which defines the coverage area of the homeless services LAHSA performs.<sup>4</sup> LAHSA uses these findings to plan, maintain, and justify its service programs.

Four samples were needed to produce estimates of the several components of the total homeless count. The count of homeless persons at any point in time in the CoC is the sum of the following four components:

**C1** --- The number of non-adolescent homeless persons living on the street;

---

<sup>3</sup> Geographic subgroups importance for the design of samples for HC11 will be limited to those defined by Service Planning Area (SPAs), Los Angeles County Supervisorial District (SD), and the City of Los Angeles (CD). "Other defined subgroups" will be limited to those defined by any of the following: people in families, single persons, chronically homeless, with severe mental illness, with chronic substance abuse problems, veterans, with HIV/AIDS, victims of partner abuse, and with disabilities.

<sup>4</sup> The LAHSA CoC includes all of Los Angeles County except for the cities of Pasadena, Glendale and Long Beach.

**C2** --- The number of non-adolescent homeless persons living in a shelter;

**C3** --- The number of adolescents living separately from those in the street and in shelters (i.e., called more simply the “youth count”); and

**C4** --- The number of non-adolescent homeless persons living separately within the residential population as a “hidden homeless person.”<sup>5</sup>

Sampling is needed for HC11 since, except for shelter homeless counts by geographic area, complete enumeration of populations to be sampled is impractical. Based on the final draft of the HC11 Statement of Work for the SRU (sent from Robert Agans to LAHSA on October 12, 2010), the samples that were needed to estimate these components were the following:<sup>6</sup>

**S1** --- A Homeless Street Count sample of the 1,888 census tracts (CTs) in the CoC that is used to produce overall and geographic subgroup estimates of **C1**;

**S2** --- A Demographic Survey sample of non-adolescent street homeless individuals that is used in combination with count estimates from **S1** to produce other subgroup estimates of **C1**;

**S3** --- A Demographic Survey sample of non-adolescent shelter homeless individuals that is used in combination with count estimates from the LAHSA complete enumeration of the sheltered population to produce other subgroup estimates of **C2**; and

**S4** --- A sample of telephone numbers used to produce CoC and geographic subgroup estimates of **C4**.

All counts of **C2** for the CoC and its geographic subgroups were obtained from the annual CoC shelter inventory of homeless shelter residents that LAHSA completes, and are thus not subject to sampling error, although other non-sampling errors (e.g., due to measurement or nonresponse) may come into play in affecting the quality of this estimate. Other subgroup estimates of **C2** were produced using data from the complete enumeration of the shelter population and data from **S2** and **S3** combined. Finally, overall and geographic estimates of **C3** were obtained by a complete enumeration of youth conducted by LAHSA, and thus were assumed to involve no sampling error, although as with **C2**, estimates of **C2** are also likely to be subject to measurement and other non-sampling errors.

---

<sup>5</sup> Hidden homeless persons are defined by the US Department of Housing and Urban Development as those who live among, but not directly with, the residential population of a community. For example, a person who lives in the garage, in the driveway, or on the back porch of household would be considered a hidden homeless person linked to that household.

<sup>6</sup> Design summary tables for each of the four samples the SRU developed are found in Appendices B-E.

The proposed HC11 approach to sampling was largely the same as for HC09. All samples were designed using random selection aimed at producing probability samples for estimating various homeless count components. As in HC09, sample stratification was used for **S1-S4**, and cluster sampling was required for **S2** and **S3**. However, there were a few strategic sample design changes aimed primarily at avoiding some of the complexities that were found to be unnecessarily burdensome in HC09. Except for the following specific design alterations, the design of HC11 samples was the same as for HC09:

All samples were designed with consideration given to producing geographic domain estimates for the CoC and Los Angeles City, as well as by eight Service Planning Areas (SPAs), and five LA County Supervisorial Districts (SDs). (**NOTE:** 15 LA City Council Districts were also included as domains in HC09, and LAHSA may need estimates for them in HC11, but they were not directly accommodated in the development of HC11 sample designs.)

- i. As regards the definitions of sampling strata for **S1-S3**, stratification variables for **S1** and **S2** were limited to SPA and whether or not the CT was considered to be a “hotspot” of homeless activity at the time of HC11, with a separate stratum created to isolate the three CTs comprising the “Skid Row” area in the City of Los Angeles.<sup>7</sup> The Skid Row CTs were then selected with certainty in **S1** and **S2**. For **S3** the number of homeless beds (large/small) was used with SPA to define the second stratification variable used in sampling shelters. This means that there will be 17 PSU strata for **S1** and **S2**, and 16 strata for **S3**.
- ii. As in HC09 several cities in the CoC opted to not only determine homeless street counts for those members of our designed sample of 614 CTs that fell within their city limits, but for all other CTs in their city as well. Since 35 areas consisting of 27 cities and 8 communities enumerated their CTs beyond those in the sample of 614 CTs thus implying that street counts were available for a total of 922 CTs. However, the City of Los Angeles and the “other unincorporated area” of Los Angeles County only produced street counts for a non-random portion of their CTs beyond those randomly selected in the sample of 614 CTs, so the sample of 922 CTs could not be considered a valid probability sample and used to estimate **C1**. The sample of 863 CTs, including our designed sample of 614 CTs plus the complementary set of 249 CTs in the other 33 “opt-in” areas, could be considered a valid sample of the 1,888 CTs in the CoC and thereby alternatively serve as **S1** to estimate **C1**. While the sample of 863 CTs had the advantage of larger sample size, its allocation among strata was highly disproportionate and sub-optimal for its sample size. Ultimately, we used data from the sample of 863 to estimate **C1** and to calibrate sample weights for **S2**, since it did indeed produce more precise estimates of the CoC homeless street count.

---

<sup>7</sup> For HC09 strata for **S1** were defined by SPA, hotspot status, and opt-in city to form 38 strata, but managing the sample sizes for this many strata proved to be unwieldy and unnecessary, since in the end all CTs in each opt-in city were counted but not considered to be part of the homeless count sample used to estimate **C1**.

- iii. Samples **S1** and **S2** were independently selected from one another for HC11, since there was no derivable statistical benefit from this design integration in HC09, where the PSU sample for **S2** was a random subset of the sample of 647 CTs selected for **S1**.<sup>8</sup>
- iv. Stratification of the PSU sample of shelters for **S3** was by SPA and shelter size as dichotomized by the number of beds (“large” vs. “small”), with delineation for each SPA near the SPA’s median bed size to facilitate roughly equal-size strata within each SPA. Selection of the PSU sample of shelters within each stratum for **S3** was in effect by simple random sampling without replacement. Moreover, sampling rates for strata within each SPA were proportionate to the average number of beds per shelter in the stratum. The proposed design was therefore approximately PPS, but was much simpler to use given several practical problems that were experienced with PPS without-replacement selection and the allowed substitution of selected shelters for **S3** in HC09.<sup>9</sup> A comparable disproportionately allocated (quasi-PPS) stratified simple random sample of CTs was also used in choosing the first stage sample for **S2**.
- v. The target respondent sample size (of knowledgeable adults in participating households) for the telephone survey to estimate the number of hidden homeless (**C4**) was reduced from about 4,000 for HC09 to 3,000 for budgetary reasons in planning HC11.<sup>10</sup> While this reduction in size would otherwise further limit the precision of the estimates of **C4**, UNC proposed to investigate expanding the reporting frame of reference for reported hidden homeless persons in HC11 beyond the respondent’s property (as in HC09) to alternatively include both the respondent’s property and all other residential properties in the “street block neighborhood” (or SBN) surrounding the respondent’s household, and to thereby experiment with an alternative multiplicity-type estimator for C4 that casts a wider net in search of those households with the extremely rare attribute of having hidden homeless persons present on their property but also compensates for the wider reporting framework by reducing sample weights by a factor of the size of each respondent’s SBN.<sup>11</sup>

---

<sup>8</sup> While technically, this eliminates the possibility of the benefit of ratio estimation based using **C1** counts from HC11, reporting domains were so extensive in HC09 that it was impractical to recoup this statistical benefit. As it turned out, however, there would have been a practical benefit to computing sample weights for **S2** by having CT street counts from **S1** available. Therefore, for HC13 we will recommend that once again the CT sample for **S2** be a random subset of **S1**.

<sup>9</sup> Note that PPS without replacement sampling of shelters, with the “measure of size” being the number of beds in the shelter, along with equal sample cluster sizes implying approximately equal selection probabilities within each PSU stratum, was used to select **S3** in HC09.

<sup>10</sup> The actual respondent sample size was 3,390 for **S4**.

<sup>11</sup> The respondent’s SBN was intended to include all households on both sides of the street on which the respondent’s household faces, and between the first cross streets on the left and right as one faces the street from the main entrance to the respondent’s residence.. The revised phone interview for the hidden homeless survey was to include questions about the number of hidden homeless person’s SBN (based on HUD criteria) as well as an estimate of the number of households in the SBN. In reality, the SBN was operationalized to be the SBN as defined above for single-family dwellings and to include the “complex grounds” for residential situations other than single-family dwellings (e.g., apartments). See question C10 of the telephone interview questionnaire.

Since each SBN is a closed network for reporting hidden homeless persons (i.e., each household is a member of one and only one SBN), each SBN become a cluster of households for reporting hidden homeless persons.

Under this multiplicity-based alternative approach, for the any respondent (located in the  $j$ -th household in the  $i$ -th SBN), the telephone survey interview was expanded to obtain the following two counts of hidden homeless persons associated with the respondent:

- a. The number of hidden homeless persons located on the property of the respondent's household residence ( $H_{ij}^{(Residence)}$ );<sup>12</sup> and
- b. The number of hidden homeless person located on the property of all other surrounding households in the respondent's SBN ( $H_{ij}^{(Rest of SBN)}$ ).

The count of hidden homeless persons on the respondent's property (i.e.,  $Y_i = H_{ij}^{(Residence)}$ ) was used to produce the estimate of **C4** in a comparable fashion to the approach used in HC09. The sum of these two counts (i.e.,  $Y_i = [H_{ij}^{(Residence)} + H_{ij}^{(Rest of SBN)}]$ ) was used to produce the multiplicity-based estimate of **C4** for HC11.

The multiplicity-based estimation approach considered here involves using  $Y_i$ , the respondent's estimate of the number of households in his/her SBN ( $M_i$ ), and the respondent's selection probability into the phone sample ( $\pi_{ij}$ ) and its corresponding sample weight ( $W_{ij}$ ) reflecting the inverse of  $\pi_{ij}$  and appropriately adjusted and calibrated for known sources of non-sampling error (e.g., differential nonresponse in the sample). Then, following the Birnbaum-Sirken (1965) approach to multiplicity estimation,<sup>13</sup> the estimator of the overall number of hidden homeless persons in the

target population of  $N_o$  residences,  $t_{HH} = \sum_{i,j}^{N_o} H_{ij}^{(Residence)}$  from a probability sample of  $n_o$  respondents will be,

---

<sup>12</sup> Note that this is the same count that was requested in the HC09 phone survey. This implies that it will be possible to replicate the estimate for **C4** using this count, and to thus compare the revised SBN-based estimate of **C4** with the comparable estimate to that obtained in HC09.

<sup>13</sup> See Birnbaum ZW and Sirken MG (1965). "Design of Sample Surveys to Estimate the Prevalence of Rare Diseases: Three Unbiased Estimates," *Vital and Health Statistics*, PHS Publication 1000, Series 2, *Data Methods and Evaluation Methods Research*, No. 11. Hyattsville, MD, National Center for Health Statistics, Public Health Service, US Department of Health and Human Services.

$$\hat{t}_{HH} = \sum_{i,j}^{n_o} \frac{Y_i}{M_i \pi_{ij}} = \sum_{i,j}^{n_o} \frac{W_{ij}}{M_i} Y_i . \quad (1)$$

Ignoring the effects of non-sampling error (e.g., due to frame, nonresponse and measurement) and of multiple landline telephone access to households, and by applying equal sampling rates to all telephone numbers within each SBN in the continuum (since strata for telephone sampling of landline telephone numbers are formed largely by measures applicable to the immediate area in which the number is located),  $\hat{t}_{HH}$  from Equation (1) can be shown to be an unbiased estimator of  $t_{HH}$  (see Appendix G).

- vi. Stratification for **S4** was the same as in HC09 (i.e., by landline list or RDD frame source and various individual and mostly contextual phone exchange-area-level demographic characteristics expected in HC09 to predict the presence of hidden homelessness in residential households, such as median household income, % of single-family households, and other characteristics of the exchange area, census block group, or census tract in which each phone household is located). This decision was made primarily to maintain continuity in sampling approaches between HC09 and HC11, and despite the fact that there remains no conclusive evidence from HC09 sample data that the variables used to define this set of 12 strata are good predictors of hidden homelessness among the households in the CoC, and thus useful for increasing the extraordinarily low hit rate of hidden homelessness in the sample by oversampling those strata presumed to have higher concentrations of hidden homeless.

### 3. Homeless Street Count Sample (S1)

**C1** is the main overall street homeless count for the CoC as a whole, as well as for various jurisdictions within the CoC (e.g., Los Angeles City, SPAs, and county supervisorial districts or SDs). It was assumed in devising the sample design for **S1** that LAHSA will: (i) identify and negotiate arrangements with various “opt-in cities” for which homeless count estimates will be obtained for all of their CTs in exchange for their providing volunteers to help with field counting and interviewing of the homeless populations therein, (ii) develop survey questionnaires and forms in consultation with Robert Agans and Judy Perlman’s survey operations group at Rand, and (iii) in consultation from appropriate survey operations Rand staff during the planning and implementation phases, hire, train, and manage the volunteer field staff who will conduct the HC homeless street counts and DS interview of homeless persons in a high quality manner. It was also understood that the SRU would: (i) develop the design for a sample of census tracts (CTs) that meet precision requirements of 15% RSE for each SPA (sample sizes by other geographic jurisdiction will not be controlled through stratification), (ii) select the sample of CTs based on the design, (iii) reviewed the survey questionnaires and forms developed by LAHSA, and (iv) perform the initial analysis of the collected sample data to enable LAHSA to report important current findings for the CoC.

#### 3.1 Design Summary

The initial design was for the design of **S1** to be a stratified single-stage without-replacement simple random sample of 614 out of the 1,888 Census Tracts that comprise the CoC for LAHSA. However, based on comparative precision of street count estimates, an alternative probability sample of 863 CTs, including the 614 CTs plus 249 others from opt-in cities where all of their CTs were ultimately counted in January 2011, will be used to produce estimates of **C1**. The Design Summary Table for **S1** is found in Appendix A, and Appendix E contains the selection worksheet for choosing the sample of CTs.

#### 3.2 Stratification and Allocation

Stratification was used in two ways here to produce the sample of 614 CTs: (i) to improve the precision of the homeless count estimates and (ii) to control the composition of the sample by SPA to facilitate estimating homeless counts for these jurisdictions to prior specifications (RSE=15%). Sampling stratification will improve the precision of estimates from a population when the variables used to define strata are correlated with what is being measured. Based on prior homeless counts, it was expected that the HC11 CT designation of hotspot or non-hotspot would correlate with the HC11 count by CT, since by its definition a “hotspot” CT is one where there is more homelessness activity, and thus the expectation that a larger number of homeless persons will be enumerated.<sup>14</sup> For this reason the HC11 hotspot/non-hotspot designation was one of the proposed stratification variables for CTs. Using SPA and HC11 hotspot status together with a special designation of Skid Row CTs, a total of 17 strata were used to select the sample of 614 CTs for the HC11 street homeless count.

---

<sup>14</sup> All totaled, 201 of the 1,888 census tracts in the CoC were designated to be hotspots for the HC11 count. .

The other CT stratification variable in choosing the sample of 614 CTs was SPA. This variable was used for stratification mainly to control the number of CTs that would be chosen in each SPA. LAHSA was particularly interested in being able to produce estimates of acceptable precision (RSE of 15% or less) for the CoC, LA City, and by SPA. Except for SPA 2, our approach then was to meet precision requirements for each SPA, with the idea that CT sample sizes will be sufficiently great for the CoC and LA city to be able to meet the 15% RSE requirement for them as well. The 15% RSE sample size of 25 CTs was deemed too low by LAHSA staff, and was therefore increased to 53 corresponding to an RSE of 10%. The recommended overall CT sample size of 614 coming out of this allocation strategy was confirmed by LAHSA to be manageable by their field staff.

Note that there were no *a priori* design considerations set out by anyone in defining the set of 249 additional CTs that were ultimately used to estimate **C1**. They were simply defined by the set of cities and communities in the CoC that decided to “opt in” and to eventually count the number of street homeless in all of their CTs.

### 3.3 Selection and Field Operations

Simple random sampling without replacement was used to select the sample of CTs in each of the 17 strata. We applied SAS proc surveyselect to an established frame file of CTs in the CoC to randomly choose the CT sample and record their corresponding selection probabilities for subsequent weights computation. Since CT nonresponse did not occur, there was no need to select a substitute sample of CTs in each stratum. The LAHSA homeless street count of sample CTs occurred on January 25-27, 2011.

### 3.4 Sample Weights

Since there was no nonresponse in counting street homeless in the sample of 614 CTs, the sample weight for each CT in this sample was simply the inverse of its selection probability (i.e., the sampling rate for the stratum in which the CT was chosen). Sample weights for the sample of 863 CTs required a different set of implied strata for computing weights and analysis. Within each of the 16 selection strata (apart from Skid Row) for the sample of 614 CTs, there were K+1 groups of 1,888 CTs, corresponding to each of the K opt-in cities that counted all of their CTs plus one more complementary group of all CTs in the stratum that were not in one of these opt-in cities. For all of the CTs in an opt-in city the sample weight was “1” since the 1/sampling fraction = 1. The weight for each Skid Row CT was also “1.” We considered the sample CTs in the stratum but not in a fully compliant opt-in city (i.e., that counted all of its CTs) to be a simple random sample of the complementary group of CTs in each stratum that were not in one of the opt-in cities. The weight for all sample members in this complementary group was thus computed as the total number in this group on the frame of 1,888 CTs, divided by the corresponding number in the sample of 863 CTs.

#### **4. Homeless Shelter Count (No Sampling)**

The HC11 count of shelter homeless was intended to be done for all shelters in the CoC. This 100% enumeration of homeless residents was completed by LAHSA staff in the current shelters in the CoC during the period of January through May 2011.

##### 4.1 Design Summary

The shelter counts were from a 100% enumeration of shelters, and thus not subject to sampling error. This does not preclude the possibility of other sources of error in these estimates (e.g., due to measurement), however.

##### 4.2 Stratification and Allocation

The 2010 Housing Inventory Chart of emergency shelters, transitional housing and safe havens from the November 2010 SuperNOFA application was used as a base for compiling a complete shelter list in the CoC. It was vetted with input from homeless coalitions, shelter providers, and LAHSA staff.

##### 4.3 Selection and Field Operations

The night a facility reported its numbers was dependent upon where that facility was located. Agencies with programs located in Service Planning Areas (SPAs) 3 and 7 performed their counts on the night of January 25th; SPAs 1, 5, and 8 were performed on January 26th and SPAs 2, 4 and 6 were performed on January 27th. These nights corresponded with the nights of the street count. Quality checks comparing capacity to occupancy, zero count reports, prior count reports, as well as other measures were taken to improve response accuracy. In all, 368 shelters were included for the point-in-time shelter census. The response rate was 100%. See Appendix K for a tally of the shelter counts.

## 5. Demographic Survey Samples – Overview

### 5.1 Two Components of the Sample

A sample of currently homeless persons was selected for the HC11 Demographic Survey (DS) primarily to estimate the rates of membership in those homeless demographic domains for which homeless counts are required by LAHSA (e.g. chronic homeless, homeless persons with mental illness, etc.). These percentage rates of domain membership for street and shelter homeless from the DS are multiplied times corresponding homeless street or shelter count estimates to create homeless count estimates for the CoC and other geographic domains to estimate the number of homeless persons in various combinations of geographic and demographic domains (e.g., the number of chronic street homeless persons in SPA 3).

The sample of homeless persons for the DS had two main components: street homeless persons and shelter homeless persons. The sample of street homeless persons was randomly chosen from those street homeless persons found on the streets within a random sample of census tracts (CTs) within the CoC at the time of street homeless in February and March of 2011. A comparably structured two-stage sample of shelter homeless persons was chosen for the shelter homeless portion of the DS sample of homeless persons.

### 5.2 Determining Overall Sample Size and Allocation Among SPAs and Between Street and Shelter Samples within SPA for the Demographic Survey

Since the overall HC09 respondent sample size (of around 3,300 homeless persons total) and allocations targets of 2,200 street homeless persons from a sample of 125 CTs and 1,100 shelter homeless persons from a sample of 150 homeless shelters were both statistically defensible and these size allocations were confirmed by LAHSA staff to be manageable, the same sizes and allocations were used for HC11.<sup>15</sup>

Compared to HC09 first stage stratification was slightly enhanced and the selection approaches for CTs and shelters were simplified somewhat. Furthermore , the CT sample for the HC11 street sample was not a subsample of the set of CTs that were used to estimate **C1**. Also, to facilitate shelter substitution and mimic the desirable but less practically feasible PPS sampling of shelters in choosing **S3**, shelter samples in strata formed for HC11 were selected by simple random sampling without replacement based with stratum sampling rates that were proportional to PSU size within SPA. For consistency, a comparable approach was used to select the sample of CTs for **S2**.

The HC09 sample size rationale was based on achieving a 15% RSE precision goal in each SPA for six key subgroups of homeless persons (see Section 4 of the HC09 Methodology Report from UNC as well as the Overall Homeless Sample Size worksheet in *Sample Size, Precision, and Allocation for Demographic Survey.xls* for details on the sample size and allocation process).<sup>16</sup> The precision of the following six

---

<sup>15</sup> The rationale for this allocation was set out in detail in the sampling documentation for HC09 and will therefore not be repeated here.

<sup>16</sup> See Cells H30 and I30 of the “SPA Allocation and RSE” sheet in *Sample Size Precision and Allocation for Demographic Survey.xls* for computational details in producing values of the optimum street-to-shelter sample

homeless subgroups were considered: the mentally ill, substance abusers, veterans, the chronically homeless, persons with HIV/AIDS, and victims of domestic violence. However, due to their extreme rarity, sample size requirements for the latter two groups were not considered since the required sample sizes were prohibitively large.

In summary, sample allocations among SPAs and between street and shelter samples for HC11 were made fully optimum so that the sample would be as representative as possible of the target population of homeless persons in the continuum. Regrettably, these optimized allocation and the quality of the selected samples of street and shelter were diminished somewhat due to difficulties with field implementation of sample selection and interviewing. For this reason the HC11 Demographic Survey first stage sampling process for CTs and shelters was simplified and LAHSA was more committed to systematically following the shelter substitution strategy UNC devised.

---

sizes. Also, see the January 28, 2009 handwritten document on "Homeless Sample Allocation for the Demographic Survey" for methodology (p. 4 especially). Finally, see the "Street and Shelter Allocation" sheet in *Sample Size Precision and Allocation for Demographic Survey.xls* for computational details in producing values of the optimum street-to-shelter sample sizes. The final sample size allocation for the street and shelter samples depended on the number of sample CTs and shelters that LAHSA staff believed their field staff could feasibly manage for data collection in the Demographic Survey. After some deliberation, LAHSA staff determined that 125 CTs and 150 sample shelters were manageable for the street and shelter samples, respectively. A larger number of sample shelters may have been seen as feasible since the logistics of sample selection and interviewing were relatively easier in shelters.

## **6. Demographic Survey – Street Homeless Sample (S2)**

The sample of street homeless persons for the Demographic Survey was chosen randomly from those homeless persons living on the street during data collection within a stratified random sample of 125 CTs at the time of street homeless data collection, which was completed between February 7, 2011 and April 8, 2011. The sample of CTs was randomly selected from a listing of 1,888 CTs in the CoC that was available from HC09 at UNC. As in HC09, replacement (random or otherwise) of selected CTs was disallowed for the street homeless sample.

### 6.1 Design Summary

As in HC09 the proposed overall design for sampling street homeless for the HC11 Demographic Survey called for a two stage random selection of street homeless persons from a stratified (without replacement) simple random sample of 125 CTs that served as PSUs that was followed by the random (second stage) selection and interviewing of an average of 17-18 street homeless persons within each sample CT. However, unlike HC09, where the first stage CT sample for the street homeless portion of the DS was chosen as a random subset of the sample of 647 CTs that were chosen for the HC09 street count, the DS sample of street homeless persons for HC11 was selected directly from the frame of 1,888 CTs in the CoC. The CT sample for the HC11 DS was thereby separately and independently chosen from the sample of CTs of 863 CTs selected to estimate the HC11 value of **C1**. At the conclusion of data gathering and cleaning, useable respondent data were available for 2,735 street homeless persons sampled from 119 of the 125 selected CTs. The Design Summary Table for **S2** is found in Appendix B, and Appendix E contains the selection worksheet for choosing the first stage sample of CTs.

### 6.2 Stratification and Allocation

Allocation of the sample of 125 CTs was based on the HC09 Neyman allocation of the overall sample size and the optimum delineation to street and shelter samples within SPA. Average sample cluster sizes in this allocation of CTs and the prior allocation of street homeless respondents implied average respondent sample cluster sizes of around 17-18 in each SPA.

The targeted number of selected CTs in the  $h$ -th stratum ( $n_h$ ) was determined so that within each SPA the two sampling strata corresponding to HC11 hotspot and non-hotspot CTs were selected with sampling rates that are proportional to the average estimated HC09 homeless street count in the stratum ( $\bar{c}_h$ ). See the PSU selection row in Appendix B for details on how this was accomplished.

No stratification was imposed in identifying the sample of homeless persons within each sample CT.

### 6.3 Selection and Data Collection

Within each of the 125 selected CTs, a sample of street homeless persons was chosen following an approach devised jointly by LAHSA staff in consultation with Rand based the latter's prior experience in conducting field studies of homeless populations. It is my understanding that a quasi-random approach to sampling was

used here, and that it involving using CT maps to first divide the CT into about four well-defined geographic segments defined by internal streets. Starting somewhere within one of these segments and proceeding on to the next segment(s) in succession as needed, field staff were instructed to systematically comb through each segment in turn, and to interview all homeless street people at the time of data gathering until they completed the number of interviews assigned (by UNC) for that CT. Since there is no direct way to determine within-CT selection probabilities for homeless person based on this sampling approach, we have assumed that in effect as simple random sample of homeless persons was chosen in each CT from a set of homeless persons of size equaling the best available estimate of the total number of street homeless persons in the CT.

While in HC09 the reality of the sampling and interviewing operation was that not all CTs were visited for various reasons (e.g., the location was considered too remote, there was too large an area to cover, too few homeless persons, etc.), LAHSA agreed to complete sampling and interviewing work per these specifications in all 125 CTs for HC11.<sup>17</sup>

#### 6.4 Sample Weights

A sample weight (i.e., a nonresponse adjusted “base weight”) for each individual homeless respondents in the street segment of the Demographic Survey was computed for each survey respondent in two basic steps: (1) compute the pre-calibration weight as the inverse of the respondent’s overall nonresponse-adjusted selection probability, which is the probability of selecting its CT (i.e., the CT sampling rate within its PSU stratum) times the probability of the respondent being selected and responding within its CT;<sup>18</sup> and (2) calibrate the adjusted base weight so that the calibrated final weights, when summed among respondents in each PSU stratum (i.e., SPA by HC11 hotspot status indicator with a separate stratum for Skid Row), equals the final HC11 Homeless Count estimates of C1 by stratum for the street count.

---

<sup>17</sup> HC09 interviews were completed in 109 of the originally selected 125 sample CTs.

<sup>18</sup> The second stage probability for any sample CT adjusted for nonresponse was estimated as the final number of completed interviews that became part of the street homeless DS respondent dataset, divided by the best estimate of the number of homeless persons in the CT at the time of sampling (i.e., use one of the following in order of preference: the HC11 field count if the CT was selected in the HC11 street count sample, the HC09 count if the CT was selected in the HC09 street count sample, the HC07 field count if the CT was selected in the HC07 street count sample, or the HC07 estimated homeless street count value based on the modeling and prediction from fitted models based on HC07 counts and various ancillary CT measures).

## 7. Demographic Survey – Shelter Homeless Sample (S3)

The sample of shelter homeless persons for the Demographic Survey was chosen randomly from those homeless persons residing in a stratified simple random sample of shelters just prior to shelter homeless data collection, which was completed between February 7, 2011 and April 8, 2011. The sample of shelters was randomly selected from a listing of 368 CoC homeless shelters compiled by LAHSA staff (Mark Silverbush) in early October 2010. The following types of shelters will be considered eligible by LAHSA staff: emergency shelters, transitional housing, winter shelter program shelters, safe havens, and year round program shelters.

### 7.1 Design Summary

As in HC09 the proposed overall design for sampling street homeless for the HC11 Demographic Survey called for a two stage random selection of shelter homeless persons with shelter as the PSU and homeless person, bed, or room within shelters as the SSU. At LAHSA's request, UNC developed a shelter substitution plan to deal with shelter-level non-participation in the DS. The initial sample of 150 shelters was a stratified sample of shelters chosen by simple random sampling without replacement in each sampling stratum. In the  $h$ -th of these strata the initial sample of  $n_h$  shelters was the first  $n_h$  shelters on a randomly sorted frame list of the  $N_h$  shelters in the stratum. Within each participating shelter, UNC designated a number of completed interviews was randomly obtained from a complete roster of residents, rooms, or beds. After applying the substitution plan as described in Section 6.3 for each stratum, the plan was for exactly 150 shelters to yield a total of about 1,100 respondent interviews from the shelter homeless. At the conclusion of data gathering and cleaning, useable respondent data were available for 850 shelter homeless persons sampled from 126 participating shelters. The Design Summary Table for S3 is found in Appendix C, and Appendix E contains the selection worksheet for choosing the first stage sample of shelters.

### 7.2 Stratification and Allocation

As with the CT sample for the street homeless portion of the Demographic Survey, allocation of the sample of 150 shelters among 16 strata formed by the cross-classification of SPA and bed-size (large/small) will be based on the HC09 Neyman allocation of the overall sample size among SPAs and yield a comparable proxy-PPS sample of shelters in each SPA. Stratum-specific average sample cluster sizes in this sample of shelters were designed to yield an overall average sample cluster size of 7-8 shelter homeless persons.

The targeted number of selected shelters in the  $h$ -th stratum ( $n_h$ ) of this sample were determined so that within each SPA shelters from the two sampling strata corresponding to larger and small bed-size shelters will be selected with sampling rates that are proportional to the average estimated HC09 homeless shelter count in the stratum ( $\bar{c}_h$ ). See the PSU selection row in Appendix C for details on how this was accomplished.

No stratification will be imposed in choosing the sample of homeless persons within each sample shelter.

### 7.3 Selection and Data Collection

In each sampling stratum the initial assigned sample of  $n_h$  shelters was the first  $n_h$  shelters on a randomly sorted list of  $N_h$  shelters in the stratum. Thus, in effect the initial sample in the  $h$ -th stratum was a simple random (without replacement) sample of shelters. As in HC09, random replacement for shelter nonresponse due to refusal or process infeasibility were allowed and in some instances invoked. However, a strict replacement strategy was installed for HC11 and was carefully implemented in the field. Selected shelters and replacements were identified by randomly permuting the list of shelters in each sampling stratum. If  $n_h$  represents the targeted number of shelter participants in the  $h$ -th sampling stratum, then the first  $n_h$  were contacted initially, a pre-determined shelter recruitment protocol invoked, and if after fully implementing the recruitment protocol an initially assigned shelter became a non-participant, the next shelter on the randomly sorted list in the stratum was assigned by UNC staff as the replacement to be recruited by LAHSA field staff in place of the non-participant. The recruitment and replacement process was designed to be continued until exactly  $n_h$  shelters participate in the DS. The final nonresponse-adjusted selection probability for each shelter within the  $h$ -th stratum could then be computed as  $n_h$  divided by  $N_h$ , the number of frame-listed shelters in that stratum.

SRU staff provided LAHSA field staff with a designated number of homeless interviews to complete within each sample shelter, so that the average number of completes per shelter would average out to be around 7-8. Since shelters with fewer expected homeless persons could not produce this many respondents, larger numbers of assigned homeless interviews were assigned to the larger sample shelters. It was also expected that 20-30% of encountered homeless persons might not be willing to participate, so sample attrition was figured into the process of determining targeted numbers of completed interviews for sample shelters.

The HC11 plan to sample homeless persons within each selected shelter was developed for HC09 jointly by SRU and LAHSA staff. The SRU initially developed a conceptual design, and LAHSA adapted it to make it workable in the field. This same development approach was followed HC11.

The HC11 within-shelter sampling plan called for doing the sampling and interviewing in the early evening hours so that homeless persons would be more likely to have checked into the shelter for the night and thus be identifiable. The mechanics of selecting homeless persons involved first creating a listing of all residents the night of interviewing, as a first priority. If a roster of residents could not be obtained, a list of beds or rooms was produced as an alternative. Interviewers were asked to record the within-shelter sampling unit and were given a sequence of random numbers to use to select entries from whatever list was used. If rooms were chosen, interviewers were asked to invite all persons in each selected room to be interviewed. Selection continued until the designated number of completed interviews was obtained from the shelter. To be able to assess the level of nonresponse in the shelter homeless sample, interviewer teams were instructed to also record: (i) the number of homeless persons who are selected and (ii) the number of homeless person who are interviewed in each shelter. Unfortunately, LAHSA field staff did not fully record this sampling-related information in shelters.

#### 7.4 Sample Weights

A sample weight (i.e., a nonresponse adjusted “base weight”) for each individual homeless respondents in the shelter portion of the Demographic Survey was computed for each survey respondent in two basic steps: (1) compute the pre-calibration weight as the inverse of the respondent’s overall nonresponse-adjusted selection probability, which is the probability of selecting the shelter in which the respondent was found (i.e., the shelter sampling rate within its PSU stratum) times the probability of the respondent being selected and responding within its CT;<sup>19</sup> and (2) calibrate the adjusted base weight so that the calibrated final weights, when summed among respondents in each PSU stratum (i.e., SPA by bed-size indicator), equals the final HC11 Homeless Count estimates of **C2** by stratum for the shelter count.

---

<sup>19</sup> The second stage probability for any sample shelter adjusted for nonresponse was estimated with first priority as the product of the following two ratios: (i) the number of selected entries selected from the list of residents/beds/rooms divided by the total number of entries on the shelter’s list of residents/beds/rooms, and (ii) the final number of completed interviews that became part of the shelter homeless DS respondent dataset divided by total number of shelter homeless persons in the shelter that were approached to complete a DS interview. If information to compute the above two ratios was not recorded by LAHSA field staff, we followed an approach comparable to that used to determine the nonresponse-adjusted within-CT selection probability for the DS street sample, with the HC11 count of homeless residents in the shelter as the denominator of the computed ratio.

## 8. Telephone Survey – Hidden Homeless

A random digit dialing (RDD) telephone survey was conducted to estimate the number of “hidden homeless” persons in the CoC for HC11.<sup>20</sup> Doing so required sampling landline telephone numbers in the CoC.<sup>21</sup> As in HC09, specially trained UNC interviewers recruited a residential sample of households to complete a “hidden homeless interview” with a knowledgeable adult from the household. The interview included questions to determine if and how many hidden homeless persons were connected somehow to the household. In HC09 the geographic context of reporting hidden homeless persons was limited to the property on which the respondent’s household was located. New in HC11 was the addition of questions to also determine how many hidden homeless persons live at other addresses within the respondent’s immediate neighborhood, or “street block neighborhood” (SBN) as we previously defined it.<sup>22</sup> Our expectation was that “multiplicity,” or network reporting approach to estimation using reported information on hidden homeless persons reported on the respondent’s property and in the immediate neighborhood, would identify a significantly larger number of hidden homeless persons and thus with appropriate weight adjustments to account for the size in households in the neighborhood, improve the precision of our estimates of the number of hidden homeless persons in the CoC.

### 8.1 Design Summary

Sample households for the two types of interviews were identified from a stratified and disproportionately allocated standard list-assisted RDD sample of landline telephone numbers from our regular telephone sampling vendor. Since there were an insufficient number of discovered hidden homeless in the HC09 telephone sample to modify our stratification strategy and sample allocation approach, Bill Kalsbeek proposed to also examine the statistical utility of the multiplicity approach to estimating the number of hidden homeless persons in the CoC (**C4**). The Design Summary Table for **S4** is found in Appendix D.

### 8.2 Stratification and Allocation

We used the same sampling strata for selecting telephone numbers for this survey as in HC09. To identify predictors of hidden homelessness in the general population in defining the HC09 strata, we consulted with staff at HUD, its telephone survey contractor (Abt Associates), and a nationally recognized expert on homelessness (Marty Burt, from the Urban Institute, who has studied hidden homelessness and various types of perilously housed persons). This consultation led to the identification of several possible predictors

---

<sup>20</sup> A “hidden homeless” person as defined by the US Department of Housing and Urban Development (HUD) as one who lives on the household property but not with the residents per se (e.g., in the garage, outside on a porch or the lawn, etc.) The questions in the hidden homeless interview applied these criteria.

<sup>21</sup> Including a cell phone sample to include households with cell phone only access was considered for HC11. It was determined that there were insufficient resources to include a cell-only sample with the landline sample.

<sup>22</sup> An “immediate neighborhood” here refers to all households in immediate geographic proximity to the respondents household, and close enough that the respondent would know about hidden homeless persons living at these addresses.

of hidden homelessness from which we chose the best ones that were available to us through data available to our telephone sampling vendor. Stratification for HC11 ultimately involved characteristics of the telephone number, or the local area in which the telephone number was located, that were thought to be predictive of whether or not the household would have hidden homeless persons present, including: the median household income of the EA in which the telephone number is located (and delineated into “high” and “low” designations at \$50,680), the percent of single-family households in the EA (and delineated into “high” and “low” designations at 60%), a count of the number of item predictors, referred to as the directory listing’s “item predictor sum” (IPS), that could be determined based on information available to our vendor for only directory-listed telephone numbers. The following items, thought to increase the chances that a hidden homeless person would be found at the household, were used to determine a directory listing’s IPS:

- Single Family Dwelling Unit? Yes=1; No=0;
- African American? Yes=1; No=0;
- Above the 80th %ile in current residence? Yes=1; No=0;
- Below 20%ile on HH income? Yes=1; No=0;
- In a BG (or CT, if only available at this level) that is above the 80th %ile on percent vacancy rate? Yes=1; No=0; and
- In a Census Tract that is above the 80th %ile on rate of street homeless count per 100,000 population members as of the 2000 Census? Yes=1; No=0.

Based on the distribution of IPS for all listed telephone numbers on the frame, we considered the IPS to be “low” if  $IPS < 2$  and to be “high” if  $IPS \geq 2$  (see *LA Homeless Telephone Sampling Specifications\_3\_5\_09.xls* that was attached to the first of five orders placed with Genesys on 3/6/09). The resulting 12 strata used for telephone sampling are described in Appendix F.

### 8.3 Pilot Testing of CATI Instrument

For the pilot study, 2,500 random digit dial telephone numbers within the Los Angeles Continuum of Care were placed in calling on December 14 and were called until December 29, 2010. Of those telephone numbers, 1,662 were finalized as ineligible, 55 as refusals, 747 were given an unknown status because eligibility was never determined, and 36 cases resulted in completed interviews. Interviews were completed with a knowledgeable adult residing within the household.

After reviewing the pilot data and talking to the interviewers, two important issues were revealed: i) the purpose of the study needed to be clearer; and ii) the estimated time to complete the interview needs to be reduced in keeping with the HC11 instrument, which was shortened substantially when we cut out the section on attitudes toward the homeless and homelessness used in HC09. Solutions to these problems were to: i) shorten the introduction and provide a better hook for completing the survey, and ii) state up-front that the interview will take less than 3-4 minutes instead of 10 (See Appendix H). Other than these minor changes, the screener changed very little from the one used in 2009.

The CATI instrument, however, changed substantially to improve the flow of the telephone interview. Most of the demographic questions were moved to the back of the instrument to build better rapport with the respondent and to help "legitimize" asking about monthly rent or mortgage expenses. Some of the language in the instrument was changed to make it more conversational. The biggest change to the hidden homeless question, was to preface it with "not including dependents or adult children". The HC11 question read:

*Not including dependents or adult children, is there anyone living with you or staying on your property because they do not have a regular or adequate place to stay due to a lack of money or other means of support?*

This change made it clearer that we were excluding dependents/children, but we still followed up each hidden homeless case with question about the householder's relationship to him or her. The response options for number of days on premise (B50) were changed to make them mutually exclusive and length of time the hidden homeless person could stay on the property now codes "indefinite" responses as "don't know." The questions on neighborhood hidden homeless piloted well, but went through major reconstruction to simplify telephone administration. The previous version read:

*Now I'd like to ask you some questions about your neighborhood. Have you seen anyone staying [on your neighbors' property (IF X10 =1)] [in your complex (IF X10 >1)] who you believe does not have a regular or adequate place to stay due to a lack of money or other means of support? For this questions, your [neighborhood includes houses on both sides of the street confined by two intersection streets] OR [complex includes all the housing units in your complex or development]. INTERVIEWER NOTE: THIS DOES NOT INCLUDE DEPENDENTS OR ADULT CHILDREN.*

The new version read:

*Now I'd like to ask you some questions about the houses on your block. Have you seen anyone who appears to be homeless staying [on your neighbors' property (IF X10 =1)] [on the complex grounds (IF X10 >1)] [WHO YOU BELIEVE DOES NOT HAVE A REGULAR OR ADEQUATE PLACE TO STAY DUE TO A LACK OF MONEY OR OTHER MEANS OF SUPPORT]? For this question, your [neighborhood block includes houses on both sides of the street confined by the closest intersection in either direction] OR [complex includes all the housing units in your complex or development].*

By capturing neighborhood hidden homeless, we hoped to improve the overall hidden homeless estimate with less error variance around the estimates. These added questions, however, did not detract from the aim of identifying hidden homeless on an individual's property nor did not detract from the estimate made in 2009. We have reproduced the same approach in 2009 and now can decide if the neighborhood questions add to the precision of our hidden homeless estimate or not.

#### 8.4 Recruitment and Training for CATI Survey

Many interviewers were recruited for data collection according to standard SRU procedures. Interviewer recruitment was overseen by supervisory staff and followed the sequence outlined below. First, interviewer

employment announcements instructed interested individuals to leave voice mail messages on the SRU's job line, fax a résumé, or email one of the calling center supervisors. Callers were screened for voice quality, phone presence and adherence to instructions. Successfully screened applicants were invited to an on-site interview. This part of the recruitment process included a mock telephone interview in which the applicant was required to administer a brief CATI health interview. Those applicants who performed well on the applicant evaluation form, which evaluates telephone manner, computer skills and professional demeanor, were asked to attend general interviewer training.

Prior to data collection, all interviewers completed training for both general and study-specific interviewing procedures. The agenda for general training includes an introduction to the SRU's operation and guidelines as well as University employment procedures and policies. Interviewers are required to sign a statement of confidentiality assuring the SRU that all data collected for the survey will be held in the strictest confidence. Most of general training addresses basic interviewing techniques and CATI skills, including delivering questionnaire introductions, administering questions in a standardized manner, coding call outcomes, and scheduling callbacks. Techniques for dealing with reluctance and refusal are also presented and covered in the training manual. Training on these issues is accomplished through a variety of training methods such as instruction, discussion, role-playing, and training videos. For example, trainees take part in role-playing to become familiar with and rehearse a variety of refusal situations. Interviewers complete practice interviews at the conclusion of general interviewer training and are then required to pass a quiz covering all aspects of training.

Study-specific training included an in-depth item-by-item review of the survey questionnaire to highlight measurement objectives and specific instructions for administering the survey instrument. Upon completion of study-specific training, interviewers were required to successfully administer a mock interview with a supervisor. This interview was designed to test interviewer aptitude in responding to questions and to assess interviewer knowledge of the survey questionnaire and specific item instructions.

### 8.5 CATI Survey Procedures

All totaled, 32,826 randomly selected telephone numbers were worked with the goal of completing 3,000 hidden homeless interviews. The overall selected sample of telephone numbers was disproportionately allocated among the 12 strata, following a similar allocation pattern of disproportionality that was observed in the HC09 survey. At the conclusion of the three month calling period, a total of 3,390 respondent interviews were completed.

Data collection took place from January 16, 2011 to April 10, 2011. The SRU has an advanced CATI operation consisting of 42 interviewer workstations and three monitoring stations. Supervisors and clients can silently monitor interviewers' audio and keyed responses from computers in the monitoring room. This monitoring capability helps ensure that data collection for the study meets the highest quality standards. During data collection, interviewing took place Saturday through Thursday (EST). Monday through Thursday calling typically ran from 12 noon to 12 midnight. Saturday sessions occurred between 1:30 pm until 5:30 pm. Sunday shifts typically ran from 5:30 pm to 12 midnight.

In addition to questionnaire programming, the SRU also utilizes Blaise's (Version 4.5, 2002) call scheduling capabilities to maximize the probability of contacting potential respondents. A central file server takes sample telephone numbers and arranges automatic call scheduling for interviewer administration. The system enables calls to be scheduled so that different times of the day and week are represented. In this study, no cases were withdrawn from calling until a minimum of 8 unsuccessful call attempts were made and there was at least one weekend call, one evening call and one daytime call made. Calls can also be scheduled at times specified by the respondent. This ensures that calls are made at optimum times.

SRU supervisors closely monitor data collection to ensure that data are being collected and entered correctly, according to guidelines and policies reviewed in training. All respondents are notified that interviews may be monitored for interviewer training and evaluation purposes. As part of SRU efforts to maximize data quality, each interviewer is provided a written evaluation every two weeks. Interviewers are evaluated on their interviewing skills, such as reading questions and responses exactly as written, using probing and clarification techniques, and conducting the interview at an appropriate pace. In addition, they are evaluated on study-specific issues and work manner. Study-specific items include knowledge of the study and study goals and the ability to answer study-specific questions clearly. Work manner includes administering a confident, professional interview, using sound judgment, providing accurate information about the call, and accurately recording call outcomes.

In addition, several steps were taken to both reduce the occurrence of refusals and to improve refusal conversion. First, we attempted to minimize refusals by introducing techniques for dealing with reluctance and refusal during general interviewer training. This was often accomplished through role-playing sessions that enable trainees to become familiar with and to rehearse a variety of refusal situations. Upon encountering a refusal, interviewers documented the following information for each refusal: reason for the refusal, the point in the interview at which the refusal occurred, and the gender and approximate age of the respondent. Refusal documentation is standard procedure at the SRU because it enables the next interviewer, the refusal converter, to tailor her approach in eliciting participation from the potential respondent, thereby optimizing the likelihood of conversion. Finally, as part of interviewer monitoring, interviewers' individual refusal rates were closely watched. Only experienced refusal converters re-contact respondents who initially refuse.

#### 8.6 CATI Survey Final Outcomes and Response Rates

The final outcomes from calling may be grouped into four broad categories (see Table 1) that are used to calculate the overall response rate: (i) a complete interview ( $I=3,390$ ); (ii) not eligible ( $NE=13,503$ ) because the telephone numbers were found to be nonworking, dedicated fax or computer lines, or reached a business/ cell line; (iii) no interview or response from an eligible household ( $NR=2,593$ ); or (iv) unknown or indeterminate ( $U=13,340$ ) because we never had the opportunity to talk to a real person or someone in the household refused participation before we could verify eligibility.

Table 1. Overall Grouping of Final Dispositions for Hidden Homeless Survey

OUTCOME	STRATA												Totals
	1	2	3	4	5	6	7	8	9	10	11	12	
I	590	379	608	209	151	39	85	88	440	254	316	231	3,390
NR	518	357	467	94	120	32	50	48	378	190	192	147	2,593
NE	1147	859	838	289	3150	1056	1670	2795	662	441	271	324	13,503
U	1983	1563	2047	685	1085	322	532	735	1497	916	1027	948	13,340
													32,826

### 8.6.1 Response Rates

The response rate is basically the number of completed interviews divided by the number of eligible households in the sample. We calculated our response rates based on the American Association for Public Opinion Research (AAPOR) Standard Definitions (2011). Weighted and unweighted response rate formulas are presented below and were determined from numbers coming from Table 1 and Appendix I.

RR4 takes the unknown eligibility numbers (U) into account by determining which proportion of them, if contacted, should be eligible. To do this, we must determine “e” or the estimated proportion of cases of unknown eligibility that may be eligible if called an indeterminate number of times. The formula we used to calculate “e” was:

$$e = \frac{nU - U - NE}{nU - U} = \frac{32,826 - 13,340 - 13,503}{32,826 - 13,340} = 0.307$$

With e defined, we can calculate RR4:

$$\text{RR4} = (100) \frac{I}{I + NR + e(U)} = (100) \frac{3390}{3390 + 2593 + (12657)(0.307)} = 33.6\%$$

RR6 assumes that  $e = 0$  or that there were no eligible cases among the unknowns. The response rate formula simplifies to:

$$RR6 = \frac{I}{I + NR} = \frac{3390}{3390 + 2593} = 56.7\%$$

The true response rate is probably somewhere between 56.7% and 33.6%, but the response rate that is typically reported in scholarly reports and journals is RR4 or 33.6%.

### 8.6.2 Weighted Response Rates

The weighted response rate is computed by multiplying the unweighted counts for the targeted and RDD frames by the sampling weight. It gives a better sense of what the response rate would have been if the entire population had been called. The formulas are given below, where 1 through 12 subscripts refers to the 12 sampling strata used (4 in RDD and 8 in targeted). First we must determine what proportion of unknown cases should have been determined eligible, again if called an indeterminate number of times. To determine that, we calculate  $e$ :

$$e = \frac{[\sum(nU_{1-12}wU_{1-12})] - [\sum(U_{1-12}wU_{1-12})] - [\sum(NE_{1-12}wU_{1-12})]}{[\sum(nU_{1-12}wU_{1-12})] - [\sum(U_{1-12}wU_{1-12})]} = 0.127$$

With  $e$  defined, we can calculate the weighted response rate as:

$$RR4 = \frac{[\sum(I_{1-12}wU_{1-12}) + \sum(P_{1-12}wU_{1-12})]}{[\sum(I_{1-12}wU_{1-12}) + \sum(P_{1-12}wU_{1-12})] + [\sum(NR_{1-12}wU_{1-12})] + e[\sum U_{1-12}(wU_{1-12})]} = 42.6\%$$

$$\text{RR6} = \frac{(\sum(I_{1-12}wU_{1-12}) + \sum(P_{1-12}wU_{1-12}))}{[\sum(I_{1-12}wU_{1-12}) + \sum(P_{1-12}wU_{1-12})] + [\sum(NR_{1-12}wU_{1-12})]} = 59.3\%$$

Table 2. Overall Response Rates for Hidden Homeless Survey

Response Rate	UNWEIGHTED	WEIGHTED
APPOR RR4	34%	43%
APPOR RR6	57%	59%

### 8.7 CATI Survey Final Sample Weights

SRU's standard three-step sample weighting procedure (involving first computing a base weight, then a nonresponse adjustment, and then sample calibration) was followed in producing sample weights for both the hidden homeless and random adult samples (Kalsbeek and Agans, 2007).<sup>23</sup> A base weight for the hidden homeless sample of households was first computed using the sampling rate for telephone numbers in each stratum, accounting for the portion of the stratum samples that were place in calling, and the number of phone lines reaching the household. The base weight was then adjusted for differential household-level nonresponse among sampling strata using the inverse of the stratum-specific-household-level RR4 response rate as the adjustment factor. The nonresponse-adjusted household sample weight was then calibrated to household counts for the CoC as estimated from the American Community Survey 2009 sample by (i) the race-ethnicity of the reference person/ knowledgeable adult (white non-Hispanic/Hispanic/Other), (ii) the type of dwelling (single-family or not), and (iii) the education of the reference person/knowledgeable adult (< college bachelor's degree vs. ≥ a college bachelor's degree). The standard multiplicative effect of variable sample weights ( $M_{eff,w}$ )<sup>24</sup> was then computed to check for the need to trim weights to compensate for the incremental effect of variable weights on the variance of estimates as recommended by Potter<sup>25</sup>.

## 9. Producing Estimates for 2011 Homeless Count

### 9.1 Street Count Estimates

HC11 street estimates were produced in SUDAAN (Version 10, RTI International), a statistical software package that is used to analyze data from complex sample surveys. SUDAAN not only produces point estimates from survey data, but also enables us to compute the appropriate standard errors of these estimates using an appropriate survey design. SUDAAN is the only software package that offers both Taylor series linearization and replication methods (BRR and Jackknife) for robust variance estimation of descriptive statistics, whereas most general-purpose statistical packages do not adequately consider the sampling design aspects in the statistical analyses. Estimated street totals and their associated standard errors were produced using the DESCRIPT Procedures in SUDAAN. Unsheltered street counts were extrapolated using actual accounts from sampled tracts which took into account how the sample was drawn (i.e., probability of selection and stratification). Homeless counts for opt-in cities and the separate youth count were not part of the sample design. Consequently, the opt-in city counts did not contribute to the total unsheltered street counts. Though the separate youth count conducted by LAHSA in March was not part of the sample design, the counts were part of the HC11 total and simply taken at face-value—no extrapolation or standard errors are associated with these youth counts. See Appendix J for the unsheltered street estimates using SUDAAN. Also, relative standard errors (RSE) are provided as a measure of quality which are expressed in percentages (i.e., the lower the RSE, the better the estimate).

An important component of the unsheltered street estimates were producing good estimates for the number of people assumed to be in cars, vans/campers, tents and encampments. Given that volunteers could not determine these numbers during the January street counts, estimates had to be produced and multiplied by number of times such observations occurred. These so-called conversion factors were based on data gathered in the demographic survey that asked respondents to estimate the number of people that typically stayed with them under such circumstances. The weighted estimates from the demographic survey produced the following conversion factors for HC11: i) cars = 1.46; ii) vans = 1.66; iii) campers/RVs = 1.79; iv) encampment = 1.91; and v) tents=1.61. These conversion factors are assumed to be constants, and thus did not contribute to the estimated sampling error of our estimates. See Appendix J for all street count estimates.

#### 9.1.1 Street Family Count Estimates

In 2009, we realized that street count family estimates were being underestimated due to the likelihood that some families were somewhat sheltered on the streets by seeking shelter in cars, vans, campers, and encampments. To produce conversion factors for this scenario, we again used results from the demographic survey, but split estimates based on the likelihood that a family was present, and when present the average family size. Based on the HC11 demographic survey, we estimates that 6 percent of people in tent were likely to be families, 5 percent encampment dwellers were likely to be families, 15 percent of families were residing in cars, 9 percent in vans, and 7 percent in campers. Individual and family size estimates also changed as seen in Table 3.

Table 3. Family and Individual Conversion Factors based on Observable Street Conditions

DWELLING TYPE	Family Conversion Factor	Individual Conversion Factor
Encampment	4.46	1.81
Car	3.13	1.17
Van	3.97	1.43
Camper/RV	3.23	1.69
Tent	2.74	1.55

## 9.2 Hidden Homeless Estimates

Hidden homeless estimates were also produced in SUDAAN using the crosstabs procedure in a with replace (wr) design that was nested by stratum and used sample weights that account for varying selection probabilities in the telephone sample and that partially offset the biasing effects of nonresponse. The CoC-wide hidden homeless weighted estimate was 10,800 (RSE = 16%) and was based on the entire sample of 3,390 completed interviews. Again, a household could only qualify as having a hidden homeless person if they had someone living on their property in an unconverted garage, a back porch, or in an encampment, camper or car. Persons residing within the household were not counted. These individuals were considered homeless by HUD and estimated counts were added to the CoC, SPA, SD (supervisorial district) and CD (city council districts) counts if the relative standard error was less than or equal to 30%. Doubled-up or precariously housed was defined as a person who was staying with the household because he or she had no other regular or adequate place to stay due to a lack of money or other means of support and who was sleeping inside the house for a period of 15-90 days. The CoC-wide estimate for precariously housed was 30,944 (RSE= 22) but were not considered homeless by HUD definitions so they were not be added to the CoC, SPA, SD, or CD counts. At-risk of literal homelessness was defined as a person who was staying with household because he or she had no other regular or adequate place to stay due to a lack of money or other means of support and who was sleeping inside the house, and had to leave in the premise in fourteen days or less. The estimate generated at the CoC-wide level was 7,827 but was considered unstable because the relative standard error was somewhat high (RSE=41). This estimate, like the precariously housed, were not considered homeless by HUD definitions so they were not be added to the CoC, SPA, SD, or CD counts.

Experience from HC09 revealed that hidden homelessness in the residential population in the CoC is extraordinarily rare. This rarity, even with a relatively large number of sample respondents, contributed to highly imprecise estimates of **C4** in the CoC, and much less for population subgroups like SPAs. To uncover a large number of hidden homeless, and thereby hopefully improve the statistical quality of estimates of **C4** for HC11, UNC proposed to experiment with an alternative estimator. This experiment was conducted in a way that allowed LAHSA to have a comparable estimate of **C4** to what was produced in HC09 and to test our

new approach in which respondents not only report the number of hidden homeless at their residence (as in HC09) but also report hidden homeless person they have notices in their immediate neighborhood. Each of these immediate neighborhoods will be referred to as street block neighborhoods (or SBNs). We define the SBN for any household as the set of households whose front entrance faces the street-bounded one-block long linear segment of street on which the referent household is located.

Since, despite the name, hidden homeless persons by the HUD criteria are likely to be noticeable to neighbors (i.e., they reside in various ways and places outdoors on residential property), and since the only cost of expanding to a neighborhood frame of reference in reporting hidden homeless persons from the respondent's own residence to the respondent's immediate neighborhood, I recommended that LAHSA allow UNC to investigate the utility of this new idea in the HC11 telephone survey.<sup>26</sup>

### 9.2.1 Notation

First define the following terms to describe the SBN-based estimate of **C4** and its associated properties:

- $$N_o = \sum_{i=1}^N M_i \quad = \text{Number of household residences in the LAHSA Continuum of Care, which also serves as the target population for HC11}$$
- $N$  = Number of closed street block neighborhood (SBN) networks in the target population
- $M_i$  = Number of household residences in the  $i$ -th SBN
- $I_{ij}$  = Sample selection indicator for the  $j$ -th household in the  $i$ -th SBN  $\Rightarrow$  household selected ( $=1$ ) or not selected ( $=0$ )
- $\pi_{ij} = E(I_{ij})$  = The selection probability for the  $j$ -th survey household in the  $i$ -th SBN
- $Y_{ij}$  = The (reported) number of hidden homeless persons in the  $i$ -th SBN as reported by the respondent in the  $j$ -th survey household in that SBN
- $Y_i$  = The (actual) number of hidden homeless persons in the  $i$ -th SBN

---

<sup>26</sup> Note that initial time testing of the HC11 telephone survey questionnaire by calling room staff at the SRU revealed that the total interview length excluding the new questions to report hidden homeless person in other households in the respondent's SBN was about five (5) minutes, as compared to seven (7) minutes with the new SBN-based reporting questions included. Thus, experimenting with an SRB-based approach to estimating **C4** would not be excessively costly.

### 9.2.2 Total Number of Hidden Homeless Persons in the CoC

The goal is to estimate the total relevant number of hidden homeless persons associated with all residential households in the CoC (i.e., **C4**) from data in a standard telephone survey. The “relevant” count depends on the type of hidden homeless person for which one wishes to estimate a total count in the CoC; i.e., the total number of hidden homeless or the number of a certain type of hidden homeless person (e.g., male/female, based on information about reported hidden homeless from the telephone interview). Following an operational interpretation provided by Mark Silverbush from LAHSA of the HUD criteria for hidden homelessness, hidden (or “unsheltered”) homeless are “people who are staying on private property but sleeping in an unconverted garage, car, camper, or otherwise outdoors,” presumably on the property on which the household is located.

Let  $t_{HH}$  denote the total (relevant) hidden homeless count that is to be estimated here, with,

$$t_{HH} = \sum_{i=1}^N Y_i = \sum_{i,j}^{N_o} H_{ij}^{(Residence)} ,$$

based on the assumption that the following two items needed to estimate  $t_{HH}$  obtained from the telephone interview respondent in the  $j$ -th household from the  $i$ -th SBN are:

- i)  $H_{ij}^{(Residence)}$  = The number of hidden homeless persons located on the property of the  $ij$ -th respondent's household residence;<sup>27</sup> and
- ii)  $H_{ij}^{(Rest\ of\ SBN)}$  = The number of hidden homeless persons located on the property of the all other household residences in the  $ij$ -th respondent's SBN.

### 9.2.3 Estimation

The sum of the two counts obtained from each HC11 telephone survey respondent (i.e.,

$Y_{ij} = [H_{ij}^{(Residence)} + H_{ij}^{(Rest\ of\ SBN)}]$  is used to produce the following alternative, and hopefully

improved, estimate of  $t_{HH}$  for HC11 from a proposed overall sample of  $n_o = 3,000$  (although ultimately 3,390) household respondents:

$$\hat{t}_{HH} = \sum_{i,j}^{n_o} \frac{Y_{ij}}{M_i \pi_{ij}} = \sum_{i,j}^{n_o} W_{ij}^* Y_{ij} .. \quad (1)$$

<sup>27</sup> Note that this is the same count that was requested in the HC09 telephone survey of hidden homeless. This implies that it will be possible to replicate the estimate of **C4** using this count alone, and to thus compare the experimental SBN-based estimate of **C4** for HC11 with the comparable estimate of **C4** that was produced for HC09.

where  $W_{ij}^* = \frac{1}{M_i \pi_{ij}}$  is the multiplicity-adjusted “base sample weight” for the  $ij$ -th respondent. Note that

while  $\hat{t}_{HH}$  in this form does not explicitly account for the potentially biasing effects of measurement error in obtaining  $Y_{ij}$  and  $M_i$ , and that  $W_{ij}^*$  (and thus  $\hat{t}_{HH}$ ) can be statistically adjusted and calibrated to reduce the biasing effects of nonresponse.

and incompleteness of the telephone sampling frame (see Section 7.4 of this paper for more on adjusting sample weights). The estimator in Equation (1) is thus a form of the well-established and widely used Horvitz-Thompson estimator of a population total, with direct accommodation of the size of the SBN-based reporting context of each survey response on the number of hidden homeless in the respondent’s SBN.

#### 9.2.4 Unbiasedness

Ignoring the biasing effects of non-sampling error as mentioned above,  $\hat{t}_{HH}$  from Equation (1) can be shown to be unbiased as follows:

First we see that,

$$\begin{aligned} E(\hat{t}_{HH}) &= E\left(\sum_{i,j}^{n_o} \frac{Y_{ij}}{M_i \pi_{ij}}\right) = E\left(\sum_{i=1}^N \sum_{j=1}^{M_i} I_{ij} \left\{ \frac{Y_{ij}}{M_i \pi_{ij}} \right\}\right) \\ &= \sum_{i=1}^N \sum_{j=1}^{M_i} \left\{ \frac{Y_{ij}}{M_i \pi_{ij}} \right\} E(I_{ij}) = \sum_{i=1}^N \sum_{j=1}^{M_i} \left\{ \frac{Y_{ij}}{M_i \pi_{ij}} \right\} \pi_{ij} \\ &= \sum_{i=1}^N \sum_{j=1}^{M_i} \left\{ \frac{Y_{ij}}{M_i} \right\} \end{aligned}$$

Finally, since  $Y_{ij} = Y_i \quad \forall M_i$  households in the  $i$ -th SBN, we have (subject to residual biasing effects of non-sampling error),

$$E(\hat{t}_{HH}) = \sum_{i=1}^N \sum_{j=1}^{M_i} \left\{ \frac{Y_{ij}}{M_i} \right\} = \sum_{i=1}^N \left\{ \frac{M_i Y_i}{M_i} \right\} = \sum_{i=1}^N Y_i = t_{HH} \quad QED$$

**Table 4:** Hidden Homeless Estimate Using the Private Property Method

Raw Count	Weighted Estimate	Weight Standard Error	Relative Standard Error
13	10,800	3,421.95	32%

**Table 5:** Hidden Homeless Estimate Using the Neighborhood Method

Raw Count	Weighted Estimate	Weight Standard Error	Relative Standard Error
322	18,622	2,889.45	15.5%

### 9.3 Annualized Estimates

Annualized estimates were produced in the same manner as HC09 and guided by procedures established by Burt and Wilkins (2005). The formula was modified to facilitate production of annualized subpopulation estimates and are conceptually equivalent (see Figure 1 below).

**Figure 1:** Original Formula to Produce Annual Homeless Estimates

	A	B	C	Annual Estimate
$A + [(B * 51)(1 - C)]$	10,800	3,421.95	32%	120,072

Where,

**A** = Point-in-Time Count;

**B** = Homeless within past 7 days or new to the area in past 7 days;

**C** = Proportion who have been previously homeless in the past 12 months;

**Figure 2:** SRU Modified Formula to Produce Annual Homeless Estimates

A <sub>c</sub>	L <sub>p</sub>	C <sub>p</sub>	Annual Estimate	
A <sub>c</sub> $\left[ 1 + \left( (51 * L_p) (1 - C_p) \right) \right]$	45,423	0.04209	0.234425	120,072

Where,

A<sub>c</sub> = Point-in-Time Count;

L<sub>p</sub> = Homeless within past 7 days or new to the area in past 7 days;

C<sub>p</sub> = Proportion who have been previously homeless in the past 12 months;

The HC11 CoC annual homeless estimate, therefore, is 120,072. That is, over the course of one year LA's Continuum of Care can expect to see more than 120,000 homeless persons. The annual formula takes into account the number of people who became homeless within the last seven days or, if already homeless, if they are new to the area (B or L<sub>p</sub>). The assumption here is that this influx of homeless people is constant so it is multiple by 51 to represent the remaining weeks of the year. However, this estimate will overestimate the annual projection because some people will become homeless more than once during the year. Therefore, the annual projection is corrected by 1-C or the proportion of people homeless only once in the past year. The UNC modified formula is equivalent to the Burt and Wilkins formula and eases calculations of multiple projections.

#### 9.4 Subpopulation Estimates

To produce estimates for important homeless subpopulations such as the chronically homeless, mentally ill, substance abusers and so on, prevalence rates of the specific subpopulation among all homeless persons first needed to be estimated from the demographic survey. The overall rate for the subgroup was estimated as the weighted sum of the estimated rates for two nonoverlapping subsets of the population: those who came from areas where the sample of CTs was chosen with certainty (i.e., self-representing) and those where only a portion of the CTs were randomly sampled (i.e., non-self-representing).

In other words,

$$\hat{p}_{\text{Chronic\_Homeless}} = W_{\text{SR}} \hat{p}_{\text{SR}} + (1 - W_{\text{SR}}) \hat{p}_{\text{NSR}}$$

$$W_{\text{SR}} = \frac{\sum_{i=1}^{N_{\text{SR}}} W_i}{\sum_{i=1}^{N_{\text{SR}}} W_i + \sum_{i=1}^{N_{\text{NSR}}} W_i}$$

$$W_{\text{NSR}} = \frac{\sum_{i=1}^{N_{\text{NSR}}} W_i}{\sum_{i=1}^{N_{\text{NSR}}} W_i + \sum_{i=1}^{N_{\text{SR}}} W_i}$$

To obtain the appropriate standard errors for each rate estimate, we needed to separately estimate the standard errors for the “self-representing” (selected with certainty) sampling units and the “non-self-representing” (selected randomly) sampling units. The estimated standard error of the overall rate was computed as the following weighted average of the two standard errors of the two subgroup estimates; i.e.,

$$se(\hat{p}) = \sqrt{W_{\text{SR}}^2 se^2(\hat{p}_{\text{SR}}) + (1 - W_{\text{SR}})^2 se^2(\hat{p}_{\text{NSR}})}$$

In SUDAAN, the self-representing estimates were produced assuming a STRWR design option with each CT treated as a stratum, and the non-self-representing estimates were produced using a WR design option in SUDAAN for the two stage design that was used in the Demographic Survey. Using the WR option for the non-self-representing portion of the sample was necessary since the somewhat haphazard pattern of substitution in the field for randomly selected CTs and shelters (that either could not be worked or became nonrespondents) from the first stage of selection in the Demographic Survey made it impossible to reconstruct the pattern of marginal and joint PSU selection probabilities that would have been needed to accommodate the actual design option for SUDAAN setup (i.e., UNEQWOR). In addition to issues related to the instability of estimated standard errors due to small sample sizes associated with the smaller geographic domains for which estimates were requested, the standard errors from this portion of the sample were thus conservatively estimated (i.e., are overestimates).

Estimated subpopulation totals were the product of the prevalence rate for the subpopulation times the best available total homeless count for the estimation domain (i.e., the geographic area for which the estimate was produced). For the Continuum of Care, the total homeless count is the sum of five component parts: i) unsheltered adult homeless count; ii) unsheltered youth homeless count; iii) sheltered count; iv) separate youth count—no sample design; and v) the estimated hidden homeless count. There were no relative standard errors around the separate youth count and the shelter count, so these counts have been taken at face value. The projected unsheltered counts for adults and youths as well as the hidden homeless estimates have expressed relative standard error associated with them and service as a measure of quality. Relative standard errors (RSE) greater than 30 percent are considered unstable and such estimates should be interpreted cautiously.

<sup>1</sup> Minors are to be interviewed by proxy with a knowledgeable adult, so the respondent and OU will differ in that case.

## SAMPLE DESIGN SUMMARY FOR HC11 DEMOGRAPHIC SURVEY OF STREET HOMELESS (Continued)

Stage	Sampling Unit and Frame Source (What is being sampled and from what sampling frame?)	Stratification (Stratify by what? Which sample allocation approach?)	Sample Selection (How will random selection be used?)	Overall Respondent Sample Size
2	<b>Secondary Sampling Unit (SSU):</b> Homeless person <sup>2</sup>	<ul style="list-style-type: none"> <li>• None</li> </ul>	<ul style="list-style-type: none"> <li>• Based on a PPT slide from the LAHSA field staff training session for Demographic Survey field workers (many of whom were paid homeless veterans), it appears that the following quasi-random approach was used for selecting the second stage sample of individual homeless persons within each sample CT:           <ul style="list-style-type: none"> <li>• Divide the CT into a few (3-5) mutually exclusive and exhaustive segments with well-defined street boundaries;</li> <li>• Identify a segment to start the process, and a sequence of segments to use as needed;</li> <li>• Starting somewhere within the starting segment completely comb through the segments, looking for eligible homeless persons to interview as you go;</li> <li>• Complete an interview if you can with any encountered homeless person;</li> <li>• Continue completing interviews until you have completed the number required by UNC for the CT</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• (As in HC09) an overall sample of <b>2,200</b> homeless respondents was targeted; this amounts to an average of 17-18 responding homeless persons per sample CT</li> <li>• The final count of street homeless respondents with useable data was 2,735; these respondents came from 119 sample CTs, implying that there was CT-level nonresponse</li> </ul>

---

<sup>2</sup>Since field interviewing was mostly done from mid-morning until early afternoon in sample CTs, it is likely that sampled homeless were limited to those accessible individuals who were recognizably homeless, and raises the question of sample under-coverage of the street homeless population.

## **APPENDIX C**

### **Design Summary Table for HC11 Demographic Survey Sample Design Aimed at the Shelter Homeless (S3)**

## DESIGN SUMMARY TABLE (S3): HC11 Demographic Survey of Shelter Homeless

**Survey Population** = Homeless persons of any age who lived in shelters in the LAHSA CoC during data collection for the 2011 Demographic Survey <sup>1</sup>

**Observational Unit** = Homeless person<sup>2</sup>

**Key Measurements** = Binary (0/1) indicator of whether or not the homeless person possess the trait for which specific homeless count is sought (see Section 3 of deliverables in the HC11 Statement of Work, dated October 12, 2010)

Stage	Sampling Unit and Frame Source	Stratification (Stratify by what? Which sample allocation approach?)	Sample Selection (How will random selection be used?)	Overall Respondent Sample Size
1	<b>Primary Sampling Unit (PSU):</b> Homeless Shelter  <b>Sampling Frame:</b> List of eligible homeless shelters developed by LAHSA as a part of their inventory of shelters and institutions as of October 22,2010.	$H = 16$ strata formed by: <ul style="list-style-type: none"> <li>• 8 Service Planning Areas (SPAs)</li> <li>• Size of the shelter ("large"/"small") determined separately in each SPA based on the number of beds in the shelter:               <ul style="list-style-type: none"> <li>• Delineate large and small by sorting shelters by size within each SPA and using the [total number of beds in the SPA ]/2 as the dividing point on the ordered list (use cum(bed-size))</li> <li>• Total number of beds in large and small shelters in each SPA should be roughly the same</li> </ul> </li> <li>• Disproportionate sample allocation plan:               <ul style="list-style-type: none"> <li>• Determine how many shelters (<math>n</math>) LAHSA can practically manage (re: sampling and data collection) overall.</li> <li>• Allocate sample optimally among SPAs using the allocation developed for HC09 (see <i>HC09 Sampling Documentation.doc</i> for details)</li> <li>• Within each SPA                   <ul style="list-style-type: none"> <li>• Shelter sample size for the two HC11 hotspot/non-hotspot strata in each SPA disproportionately allocated to approximate PPS sampling within SPA</li> <li>• <math>n_h \geq 2</math> of final participating shelters in each of <math>H = 16</math> strata</li> </ul> </li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• SRS WOR selection within each of <math>H = 16</math> strata as a proxy to PPS sampling within SPA, but implemented by randomly sorting the set of shelters in each stratum (to facilitate shelter substitution that will be allowed)</li> <li>• Used sampling rates, <math>f_h = n_h / N_h</math> (for the two large/small strata within SPA) that were directly proportional to the estimated average number of shelter beds in the stratum (<math>\bar{c}_h</math>) based on information provided on the HC11 shelter frame by LAHSA</li> <li>• For the HC11 sample of shelters in each SPA,               <ul style="list-style-type: none"> <li>• I determined what <math>f_h</math> was for each of the two bed-size strata so that <math>f_h = k\bar{c}_h</math>, with <math>k</math> being some constant among the two strata. With <math>n</math>, <math>\bar{c}_h</math> and <math>f = n/N</math> determined, and the total number of CTs in the SPA (<math>N</math>) known,, I could use <math display="block">k = f / (\sum_{h=1}^2 W_h \bar{c}_h)</math> to obtain values of <math>f_h</math> and <math>n_h</math> for the two bed-size strata in each SPA</li> </ul> </li> <li>• Since shelter nonresponse was expected; substitution for shelter nonresponse was allowed with the goal of recruiting exactly <math>n_h</math> participating shelters in each stratum</li> </ul>	<ul style="list-style-type: none"> <li>• (As in HC09) <math>n = 150</math> responding shelters overall, was the target sample size for this sampling stage</li> <li>• Substitution was allowed, but only if implemented strictly as follows within each stratum:               <ul style="list-style-type: none"> <li>• A specific recruitment protocol was set for each selected/designated shelter in the sample</li> <li>• Following the randomized order of shelters in the stratum, attempt to recruit the first <math>n_h</math> shelters</li> <li>• Substitute the next available shelter on the list only after the recruitment protocol was unsuccessful</li> </ul> </li> <li>• The final number of responding shelters was <math>n=126</math>, thus implying that there was still shelter nonresponse.</li> </ul>

<sup>1</sup>Shelters as listed by LAHSA for the SRU at the time of the Demographic Survey

<sup>2</sup> Minors were to be interviewed by proxy with a knowledgeable adult, implying that the respondent and the observational unit differed in that case.

## HC11 DEMOGRAPHIC SURVEY OF SHELTER HOMELESS (Continued)

Stage	Sampling Unit and Frame Source (What is being sampled and from what sampling frame?)	Stratification (Stratify by what? Which sample allocation approach?)	Sample Selection (How will random selection be used?)	Overall Respondent Sample Size
2	<b>Secondary Sampling Unit (SSU): Homeless person<sup>3</sup></b>	<ul style="list-style-type: none"> <li>• None</li> </ul>	<ul style="list-style-type: none"> <li>• Following the HC09 sampling protocol, homeless persons were selected and interviewed as follows within each of the participating shelters:           <ul style="list-style-type: none"> <li>• Obtain or produce a numbered (i.e., 1 to N) list all N homeless residents of the shelter on the night of interviewing.</li> <li>• If a list of persons was could not be produced, then a comparably numbered list of beds or rooms in the shelter, with unique identifiers for each entry on the list, was obtained-produced.</li> <li>• Following the order of a provided random permutation of N integers (i.e., a randomly sorted list of N integers between 1 and N), identify, contact and attempt to interview the pre-assigned number of homeless persons staying at the shelter that night, or as many persons as possible.</li> <li>• Record the following on the sampling worksheet for the shelter immediately after interviewing is completed in the shelter: the sampling unit (resident/bed/room), the final number of completed interviews in that shelter, and the number of homeless persons encountered.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• (As in HC09) an overall sample of 1,100homeless respondents was targeted; thus an average of 7-8 responding homeless persons was expected per sampled shelter</li> <li>• The final count of shelter homeless respondents with useable data was 850; these respondents came from 126participating shelters</li> </ul>

---

<sup>3</sup>Sampling of homeless within shelters was limited to those homeless persons who were residing in each selected shelter at the time that interviewing was conducted in that shelter. The homeless sample in each shelter was chosen from a list of individual residents, bed, or rooms as necessary.

## **APPENDIX D**

### **Design Summary Table for HC11 Telephone Survey Sample Design Aimed at the Hidden Homeless (S4)**

**DESIGN SUMMARY TABLE (S4):**  
**Telephone Survey to Estimate the Number of Hidden Homeless (C4)**

**Eligible for Study Population =** Residential landline households in the LAHSA Continuum of Care

**Observational Unit =** Knowledgeable adult in the sampled household

**Key Measurements =** Number of hidden homeless persons on the sample household property; number of hidden homeless person in the household's immediate neighborhood

<b>Stage</b>	<b>Sampling Unit and Frame Source</b> (What is being sampled and from what sampling frame?)	<b>Stratification</b> (Stratify by what? Which sample allocation approach?)	<b>Sample Selection</b> (How will random selection be used?)	<b>Overall Sample Size</b>
1	<p><b>Primary Sampling Unit:</b> RDD or targeted directory listed landline telephone number</p> <p><b>Frame:</b> List-assisted RDD frame of telephone numbers in the set of 1,888 census tracts comprising the CoC, as maintained by Genesys</p>	<p><math>H = 12</math> strata</p> <ul style="list-style-type: none"> <li>Defined by frame source (listed/unlisted RDD) and local area information thought to be predictive of hidden homeless (i.e., median household income and % of single family households in the PN's telephone exchange area, and a count of six household and local area characteristics called the PN's "item predictor sum")</li> <li>Disproportionately allocated sample of 33,169 selected telephone numbers following the disproportionality pattern resulting from HC09 as well as calling outcomes from HC11</li> </ul>	<ul style="list-style-type: none"> <li>Simple random sampling (without replacement)</li> </ul>	<ul style="list-style-type: none"> <li>Targeted sample size was 3,000 responding knowledgeable adults from a selected sample of 33,169 telephone numbers that were placed in calling</li> <li>The actual number of completed telephone interviews was 3,390</li> </ul>

		10		12	

## **APPENDIX G**

### **Details on Proposed Alternative Approach for Estimating C4 from HC11 Telephone Sample Data (S4)**

## Background and Rationale:

Experience from HC09 revealed that hidden homelessness in the residential population in the CoC is extraordinarily rare. Indeed, only 16 homeless persons (meeting the HUD criteria for hidden homelessness) were reported in the 4,288 responding households in the HC09 telephone survey. This rarity, even with a relatively large number of sample respondents, contributed to highly imprecise estimates of **C4** in the CoC, and much less for population subgroups like SPAs.

To uncover a large number of hidden homeless, and thereby hopefully improve the statistical quality of estimates of **C4** for HC11, UNC proposed to experiment with an alternative estimator. This experiment was conducted in a way that allowed LAHSA to have a comparable estimate of **C4** to what was produced in HC09 and to test our new approach in which respondents not only report the number of hidden homeless at their residence (as in HC09) but also report hidden homeless person they have notices in their immediate neighborhood. Each of these immediate neighborhoods will be referred to as street block neighborhoods (or SBNs). I define the SBN for any household as the set of households whose front entrance faces the street-bounded one-block long linear segment of street on which the referent household is located.

Since, despite the name, hidden homeless persons by the HUD criteria are likely to be noticeable to neighbors (i.e., they reside in various ways and places outdoors on residential property), and since the only cost of expanding to a neighborhood frame of reference in reporting hidden homeless persons from the respondent's own residence to the respondent's immediate neighborhood, I recommended that LAHSA allow UNC to investigate the utility of this new idea in the HC11 telephone survey.<sup>1</sup>

## Notation:

First define the following terms to describe the RBN-based estimate of **C4** and its associated properties:

$$N_o = \sum_{i=1}^N M_i = \text{Number of household residences in the LAHSA Continuum of Care, which also serves as the target population for HC11}$$

$N$  = Number of closed street block neighborhood (SBN) networks in the target population

$M_i$  = Number of household residences in the  $i$ -th SBN

$I_{ij}$  = Sample selection indicator for the  $j$ -th household in the  $i$ -th SBN  $\Rightarrow$  household selected (=1) or not selected (=0)

$\pi_{ij} = E(I_{ij})$  = The selection probability for the  $j$ -th survey household in the  $i$ -th SBN

$Y_{ij}$  = The (reported) number of hidden homeless persons in the  $i$ -th SBN as reported by the respondent in the  $j$ -th survey household in that SBN

$Y_i$  = The (actual) number of hidden homeless persons in the  $i$ -th SBN

---

<sup>1</sup> Note that initial time testing of the HC11 telephone survey questionnaire by calling room staff at the SRU revealed that the total interview length excluding the new questions to report hidden homeless person in other households in the respondent's SBN was about five (5) minutes, as compared to seven (7) minutes with the new SBN-based reporting questions included. Thus, experimenting with an SRB-based approach to estimating **C4** would not be excessively costly.

### Total Number of Hidden Homeless Persons in the CoC:

The goal is to estimate the total relevant number of hidden homeless persons associated with all residential households in the CoC (i.e., **C4**) from data in a standard telephone survey. The “relevant” count depends on the type of hidden homeless person for which one wishes to estimate a total count in the CoC; i.e., the total number of hidden homeless or the number of a certain type of hidden homeless person (e.g., male/female, based on information about reported hidden homeless from the telephone interview). Following an operational interpretation provided by Mark Silverbush from LAHSA of the HUD criteria for hidden homelessness, hidden (or “unsheltered”) homeless are “people who are staying on private property but sleeping in an unconverted garage, car, camper, or otherwise outdoors,” presumably on the property on which the household is located.

Let  $t_{HH}$  denote the total (relevant) hidden homeless count that is to be estimated here, with,

$$t_{HH} = \sum_{i=1}^N Y_i = \sum_{i,j}^{N_o} H_{ij}^{(Residence)} ,$$

based on the assumption that the following two items needed to estimate  $t_{HH}$  obtained from the telephone interview respondent in the  $j$ -th household from the  $i$ -th SBN are:

- i)  $H_{ij}^{(Residence)}$  = The number of hidden homeless persons located on the property of the  $ij$ -th respondent's household residence;<sup>2</sup> and
- ii)  $H_{ij}^{(Rest\ of\ SBN)}$  = The number of hidden homeless persons located on the property of the all other household residences in the  $ij$ -th respondent's SBN.

### Estimation:

The sum of the two counts obtained from each HC11 telephone survey respondent (i.e.,

$Y_{ij} = [H_{ij}^{(Residence)} + H_{ij}^{(Rest\ of\ SBN)}]$  is used to produce the following alternative, and hopefully improved, estimate of  $t_{HH}$  for HC11 from a proposed overall sample of  $n_o = 3,000$  (although ultimately 3,390) household respondents:

$$\hat{t}_{HH} \equiv \sum_{i,j}^{n_o} \frac{Y_{ij}}{M_i \pi_{ij}} = \sum_{i,j}^{n_o} W_{ij}^* Y_{ij} .. \quad (1)$$

---

<sup>2</sup> Note that this is the same count that was requested in the HC09 telephone survey of hidden homeless. This implies that it will be possible to replicate the estimate of **C4** using this count alone, and to thus compare the experimental SBN-based estimate of **C4** for HC11 with the comparable estimate of **C4** that was produced for HC09.

where  $W_{ij}^* = \frac{1}{M_i \pi_{ij}}$  is the multiplicity-adjusted “base sample weight” for the  $ij$ -th respondent. Note that while  $\hat{t}_{HH}$  in this form does not explicitly account for the potentially biasing effects of measurement error in obtaining  $Y_{ij}$  and  $M_i$ , and that  $W_{ij}^*$  (and thus  $\hat{t}_{HH}$ ) can be statistically adjusted and calibrated to reduce the biasing effects of nonresponse.

and incompleteness of the telephone sampling frame (see Section 7.4 of this paper for more on adjusting sample weights). The estimator in Equation (1) is thus a form of the well-established and widely used Horvitz-Thompson estimator of a population total, with direct accommodation of the size of the SBN-based reporting context of each survey response on the number of hidden homeless in the respondent’s SBN.

#### **Unbiasedness:**

Ignoring the biasing effects of non-sampling error as mentioned above,  $\hat{t}_{HH}$  from Equation (1) can be shown to be unbiased as follows:

First we see that,

$$\begin{aligned} E(\hat{t}_{HH}) &= E\left(\sum_{i,j}^{n_o} \frac{Y_{ij}}{M_i \pi_{ij}}\right) = E\left(\sum_{i=1}^N \sum_{j=1}^{M_i} I_{ij} \left\{ \frac{Y_{ij}}{M_i \pi_{ij}} \right\}\right) \\ &= \sum_{i=1}^N \sum_{j=1}^{M_i} \left\{ \frac{Y_{ij}}{M_i \pi_{ij}} \right\} E(I_{ij}) = \sum_{i=1}^N \sum_{j=1}^{M_i} \left\{ \frac{Y_{ij}}{M_i \pi_{ij}} \right\} \pi_{ij} \\ &= \sum_{i=1}^N \sum_{j=1}^{M_i} \left\{ \frac{Y_{ij}}{M_i} \right\} \end{aligned}$$

Finally, since  $Y_{ij} = Y_i \quad \forall M_i$  households in the  $i$ -th SBN, we have (subject to residual biasing effects of non-sampling error),

$$E(\hat{t}_{HH}) = \sum_{i=1}^N \sum_{j=1}^{M_i} \left\{ \frac{Y_{ij}}{M_i} \right\} = \sum_{i=1}^N \left\{ \frac{M_i Y_i}{M_i} \right\} = \sum_{i=1}^N Y_i = t_{HH} \quad QED$$

## GLAHC 2011 HIDDEN HOMELESS SURVEY

First, I'd like to ask you a few questions about you and your household.

X10. Do you live in ...

- 1 a house (GOTO X20)
- 2 an apartment (GOTO X20)
- 3 townhome(GOTO X20)
- 4 condo(GOTO X20)
- 5 single room housing (GOTO X20)
- 6 OTHER (GOTO X11)
- 8 REFUSED
- 9 DON'T KNOW

X11. OTHER FILL-IN

\_\_\_\_ (250 CHAR TEXT)

88888 REFUSED

99999 DON'T KNOW

X20. Do you rent or own this home?

- 1 RENT
- 2 OWN
- 8 REFUSED
- 9 DON'T KNOW

A10. Not including dependent children, is there anyone living with you or staying on your property because they do not have a regular or adequate place to stay due to a lack of money or other means of support?

- 1 YES
- 2 NO (GOTO C10)
- 8 REFUSED (GOTO C10)
- 9 DON'T KNOW (C10)

A20. And how many people would that be (HOW MANY PEOPLE MEET THIS DEFINITION)?

- 1 ONE (GOTO B10)
- 2 TWO (GOTO B10\_INTRO)
- 3 THREE (GOTO B10\_INTRO)
- 4 FOUR (GOTO B10\_INTRO)
- 5 FIVE (GOTO B10\_INTRO)
- 6 SIX (GOTO B10\_INTRO)
- 7 SEVEN (GOTO B10\_INTRO)
- 8 EIGHT (GOTO B10\_INTRO)
- 9 NINE (GOTO B10\_INTRO)
- 10 TEN OR MORE (GOTO B10\_INTRO)
- 88 REFUSED (GOTO C10)
- 99 DON'T KNOW (GOTO C10)

## GLAHC 2011 HIDDEN HOMELESS SURVEY

B10\_INTRO [IF A20 > 1] I would now like to ask you some questions about these individuals [STAYING WITH YOU BECAUSE THEY DO NOT HAVE A REGULAR OR ADEQUATE PLACE TO STAY DUE TO A LACK OF MONEY OR OTHER MEANS OF SUPPORT.] First, I'd like to ask you about the youngest person...

B10. Is that person male or female?

- 1 MALE
- 2 FEMALE
- 8 REFUSED
- 9 DON'T KNOW

B20. Is that person over or under 18 years old?

- 1 OVER (GOTO B30)
- 2 UNDER (GOTO B21)
- 8 REFUSED (GOTO B30)
- 9 DON'T KNOW (GOTO B30)

B21. How old is [SHE/HE]?

- 1 5 YEARS OLD OR YOUNGER (GO TO B30)
- 2 6 - 12 YEARS OLD
- 3 13 - 17 YEARS OLD
- 8 REFUSED
- 9 DON'T KNOW

B22. Is [SHE/HE] in school?

- 1 YES
- 2 NO
- 8 REFUSED
- 9 DON'T KNOW

B23. Does [SHE/HE] receive any services, such as counseling, housing assistance or busing to and from school, because [SHE/HE] is homeless?

- 1 YES
- 2 NO
- 8 REFUSED
- 9 DON'T KNOW

B30. Is this person related to you?

- 1 YES (GOTO B35)
- 2 NO (GOTO B40)
- 8 REFUSED (GOTO B40)
- 9 DON'T KNOW (GOTO B40)

## GLAHC 2011 HIDDEN HOMELESS SURVEY

B35. What is this person's relationship to you?

\_\_\_\_\_ (250 CHAR TEXT)

88888 REFUSED

99999 DON'T KNOW

B40. Does [SHE/HE] sleep inside or outside the main house?

1 INSIDE THE MAIN HOUSE (GOTO B41)

2 OUTSIDE THE MAIN HOUSE (GOTO B43)

8 REFUSED (GOTO B50)

9 DON'T KNOW (GOTO B50)

B41. Where inside the house does [SHE/HE] usually sleep?

1 ATTIC (GOTO B47)

2 BASEMENT (GOTO B47)

3 BEDROOM (GOTO B50)

4 FAMILY ROOM, LIVING ROOM OR DEN (GOTO B50)

5 DINING ROOM OR KITCHEN (GOTO B50)

6 LAUNDRY ROOM OR OTHER INSIDE STORAGE AREA (GOTO B50)

7 OTHER AREA OF THE MAIN HOUSE (GOTO B42)

8 REFUSED

9 DON'T KNOW

B42. OTHER (PLEASE SPECIFY)

\_\_\_\_\_ (250 CHAR TEXT) (GOTO B50)

88888 REFUSED (GOTO B50)

99999 DON'T KNOW (GOTO B50)

B43. Where outside the house does [SHE/HE] usually sleep?

1 GARAGE (GOTO B47)

2 PORCH (GOTO B50)

3 CAR, TRUCK, VAN PARKED ON PROPERTY (GOTO B50)

4 RV, TRAILOR, OR CAMPER PARKED ON PROPERTY (GOTO B50)

5 TENT OR SHED OUTSIDE (GOTO B50)

6 GUEST HOUSE (GOTO B50)

7 OTHER (GOTO B44)

8 REFUSED (GOTO B50)

9 DON'T KNOW (GOTO B50)

B44. OTHER (PLEASE SPECIFY)

\_\_\_\_\_ (250 CHAR TEXT) (GOTO B50)

88888 REFUSED (GOTO B50)

99999 DON'T KNOW (GOTO B50)

## GLAHC 2011 HIDDEN HOMELESS SURVEY

B47. Have there been any major improvements made to the [INSERT ATTIC, BASEMENT OR GARAGE] to make it a living unit of its own?

- 1 YES
- 2 NO
- 8 REFUSED
- 9 DON'T KNOW

B50. How long has [SHE/HE] been staying with you or living on your property?

- 1 7 DAYS OR LESS
- 2 8 - 14 DAYS
- 3 15 - 30 DAYS
- 4 MORE THAN 1 MONTH BUT LESS THAN 3 MONTHS
- 5 3 MONTHS OR MORE BUT LESS THAN 5 MONTHS
- 6 5 MONTHS OR MORE BUT LESS THAN 12 MONTHS
- 7 ONE YEAR OR MORE
- 8 REFUSED
- 9 DON'T KNOW

[SKIP TO B70 IF B21=1: THE INDIVIDUAL IS A CHILD UNDER 5 YEARS OLD]

B60. Is there an agreement that [SHE/HE] should contribute to the household?

(SKIP IF B21=1)

- 1 YES
- 2 NO (GOTO B70)
- 8 REFUSED (GOTO B70)
- 9 DON'T KNOW (GOTO B70)

B65. How does [SHE/HE] contribute to the household? Does [SHE/HE]... (CHECK ALL THAT APPLY) (SKIP IF B21=1)

- 1 Prepare or provide food
- 2 provide childcare services
- 3 pay rent
- 4 perform household duties or responsibilities
- 5 Another kind of contribution (GOTO B66)
- 8 REFUSED
- 9 DON'T KNOW

B66. OTHER (PLEASE SPECIFY)

\_\_\_\_ (250 CHAR TEXT)

88888 REFUSED

99999 DON'T KNOW

## GLAHC 2011 HIDDEN HOMELESS SURVEY

B70. How long is [SHE/HE] allowed to stay within your household or on your property?  
[IF LENGTH OF TIME IS UNSPECIFIED OR RESPONDENT SAYS "INDEFINITELY", SELECT DON'T KNOW]

\_\_\_\_\_ DAYS \_\_\_\_\_ MONTHS \_\_\_\_\_ YEARS 88888 RF 99999 DK

B71. Does [SHE/HE] have the resources and support networks necessary to get stable Housing if [SHE/HE] leaves your home or property?

- 1 YES (GOTO B72)
- 2 NO (GOTO C10 IF A20 = 1 OR L10 IF A20 > 1)
- 8 REFUSED (GOTO C10 IF A20 = 1 OR L10 IF A20 > 1)
- 9 DON'T KNOW (GOTO C10 IF A20 = 1 OR L10 IF A20 > 1)

B72. Does [SHE/HE] have a new place to live?

- 1 YES (GOTO C10 IF A20 = 1 OR L10 IF A20 > 1)
- 2 NO (GOTO C10 IF A20 = 1 OR L10 IF A20 > 1)
- 8 REFUSED (GOTO C10 IF A20 = 1 OR L10 IF A20 > 1)
- 9 DON'T KNOW (GOTO C10 IF A20 = 1 OR L10 IF A20 > 1)

[IF A20 > 1] Now let's go on to the [next oldest / oldest] person staying with you because they do not have a regular or adequate place to stay due to a lack of money or other means of support.

[REPEAT B10 - B72 BLOCK BASED ON A20 #]

L10. Would you describe any of these people as a family; that is, having at least one adult and at least one child under the age of 18?

- 1 YES
- 2 NO (GOTO C10)
- 8 REFUSED (GOTO C10)
- 9 DON'T KNOW (GOTO C10)

L20. How many of these families are living with you? [RESPONDENT SHOULD NOT INCLUDE THEIR OWN FAMILY]

- 1 ONE (CHECK: A20 GE 2) (GOTO L30\_1 BLOCK)
- 2 TWO (CHECK:A20 GE 4) (GOTO L30\_1 BLOCK THEN L30\_2 BLOCK)
- 3 THREE (CHECK:A20 GE 6) (GOTO L30\_1, L30\_2 AND L30\_3 BLOCKS)
- 4 FOUR (CHECK:A20 GE 8) (GOTO L30\_1, L30\_2, L30\_3 AND L30\_4 BLOCKS)
- 5 FIVE OR MORE (CHECK:A20 GE 10) (GOTO L30\_1, L30\_2, L30\_3, L30\_4 AND L30\_5 BLOCKS)
- 8 REFUSED (GOTO C10)
- 9 DON'T KNOW (GOTO C10)

## GLAHC 2011 HIDDEN HOMELESS SURVEY

L30\_1. In [THIS/THE FIRST] family, can you tell me how many are...

- adult males RF DK (18 OR OLDER)  
L31\_1  adult females RF DK (18 OR OLDER)  
L32\_1  youth males RF DK (LESS THAN 18)  
L33\_1  youth females RF DK (LESS THAN 18)

L30\_2. In [THE SECOND] family, can you tell me how many are...

- adult males DK RF  
L31\_2  adult females DK RF  
L32\_2  youth males RF DK  
L33\_2  youth females RF DK

L30\_3. In [THE THIRD] family, can you tell me how many are...

- adult males RF DK  
L31\_3  adult females RF DK  
L32\_3  youth males RF DK  
L33\_3  youth females RF DK

L30\_4. In [THE FOURTH] family, can you tell me how many are...

- adult males RF DK  
L31\_4  adult females RF DK  
L32\_4  youth males RF DK  
L33\_4  youth females RF DK

L30\_5. In [THE FIFTH] family, can you tell me how many are...

- adult males RF DK  
L31\_5  adult females RF DK  
L32\_5  youth males RF DK  
L33\_5  youth females RF DK

C10. Now I'd like to ask you some questions about the houses on your block. Have you seen anyone who appears to be homeless staying [on your neighbors' property (IF X10 =1)] [on the complex grounds (IF X10 >1)] [WHO YOU BELIEVE DOES NOT HAVE A REGULAR OR ADEQUATE PLACE TO STAY DUE TO A LACK OF MONEY OR OTHER MEANS OF SUPPORT]? For this question, your [neighborhood block includes houses on both sides of the street confined by the closest intersection in either direction] OR [complex includes all the housing units in your complex or development ].

- 1 YES (GOTO C11)  
2 NO (GOTO Y60\_INTRO)  
8 REFUSED (GOTO Y60\_INTRO)  
9 DON'T KNOW (GOTO Y60\_INTRO)

## GLAHC 2011 HIDDEN HOMELESS SURVEY

C11. How recently have you seen someone like this ?

- 1 In the past 7 days (GOTO C20)
- 2 More than 7 days ago, but within the past month (GOTO Y60\_INTRO)
- 3 More than a month ago, but within the past year (GOTO Y60\_INTRO)
- 4 More than one year ago (GOTO Y60\_INTRO)
- 8 REFUSED (GOTO Y60\_INTRO)
- 9 DON'T KNOW (GOTO Y60\_INTRO)

C20. How many people were there (HOW MANY PEOPLE MEET THIS DEFINITION)?

INTERVIEWER NOTE: IF THERE ARE MULTIPLE HOMELESS ON MULTIPLE PROPERTIES, ASK RESPONDENT TO ADD UP ALL OF THEM FOR THE NEXT QUESTION.

- 1 ONE
- 2 TWO
- 3 THREE
- 4 FOUR
- 5 FIVE
- 6 SIX
- 7 SEVEN
- 8 EIGHT
- 9 NINE
- 10 TEN OR MORE
- 88 REFUSED (GOTO Y60\_INTRO)
- 99 DON'T KNOW (GOTO Y60\_INTRO)

C25. Would you say that you are *very sure*, *somewhat sure*, or *not very sure* of this number?

- 1 VERY SURE
- 2 SOMEWHAT SURE
- 3 NOT VERY SURE
- 88 REFUSED
- 99 DON'T KNOW

D10\_INTRO [IF C20 > 1] Now I'd like to ask you some questions about these individuals [STAYING IN YOUR NEIGHBORHOOD WHO YOU BELIEVE DO NOT HAVE A REGULAR OR ADEQUATE PLACE TO STAY DUE TO A LACK OF MONEY OR OTHER MEANS OF SUPPORT]. First I'd like you to think about the youngest person you have seen [WHO MEETS THIS DESCRIPTION].

## GLAHC 2011 HIDDEN HOMELESS SURVEY

D10. Is that person male or female?

- 1 MALE
- 2 FEMALE
- 8 REFUSED
- 9 DON'T KNOW

D20. Is that person over or under 18 years old?

- 1 OVER (GOTO D40)
- 2 UNDER (GOTO D21)
- 8 REFUSED (GOTO D40)
- 9 DON'T KNOW (GOTO D40)

D21. How old does [SHE/HE] appear to be?

- 1 5 YEARS OLD OR YOUNGER
- 2 6 - 12 YEARS OLD
- 3 13 - 17 YEARS OLD
- 8 REFUSED
- 9 DON'T KNOW

D40. And just to confirm, does [SHE/HE] appear to sleep inside the house or outside the house?

- 1 INSIDE THE HOUSE (GOTO D\_Recursion)
- 2 OUTSIDE THE HOUSE (GOTO D42)
- 8 REFUSED (GOTO D50)
- 9 DON'T KNOW (GOTO D50)

D42. Where outside the house does [SHE/HE] appear to sleep?

- 1 GARAGE (GOTO D47)
- 2 PORCH (GOTO D\_Recursion)
- 3 CAR, TRUCK, VAN PARKED ON PROPERTY (GOTO D\_Recursion)
- 4 RV OR CAMPER PARKED ON PROPERTY (GOTO D\_Recursion)

## GLAHC 2011 HIDDEN HOMELESS SURVEY

우선, 귀하 자신과 귀하의 가족에 대해 몇 가지 질문을 드리고자 합니다.

X10. 귀하가 사시는 곳은 ...

- 1 주택 (GOTO X20)
- 2 아파트 (GOTO X20)
- 3 타운홈 (GOTO X20)
- 4 콘도 (GOTO X20)
- 5 방 한 칸에서 거주 (GOTO X20)
- 6 기타 (GOTO X11)
- 8 모른다
- 9 헛갈린다

X11. 기타 사항

\_\_\_\_\_ (250 CHAR TEXT)

- 88888 모른다
- 99999 헛갈린다

X20. 이 거주지를 임대하십니까, 소유하십니까?

- 1 임대한다
- 2 소유한다
- 8 모른다
- 9 헛갈린다

A10. 귀하의 부양 자녀는 제외시키고, 본인과 함께 사는 사람이나 본인의 자택에 머물고 있는 사람이 돈이 없거나 다른 형태의 생계비가 없어 정기적으로 거주할 적당한 장소가 없는 사람이 있습니까?

- 1 예
- 2 아니오 (GOTO C10)
- 8 모른다 (GOTO C10)
- 9 헛갈린다 (C10)

A20. 그런 사람이 몇 명입니까? (이 정의에 부합되는 사람이 몇 사람입니까?)

- 1 하나 (GOTO B10)
- 2 둘 (GOTO B10\_INTRO)
- 3 셋 (GOTO B10\_INTRO)
- 4 넷 (GOTO B10\_INTRO)
- 5 다섯 (GOTO B10\_INTRO)
- 6 여섯 (GOTO B10\_INTRO)
- 7 일곱 (GOTO B10\_INTRO)
- 8 여덟 (GOTO B10\_INTRO)

- 9 아홉 (GOTO B10\_INTRO)
- 10 열 또는 그 이상 (GOTO B10\_INTRO)
- 88 모른다 (GOTO C10)
- 99 헛갈린다 (GOTO C10)

B10\_INTRO [IF A20 > 1] 이제 귀하게 이분들에 대한 질문을 드리고자 합니다. [돈이 없거나 다른 형태의 생계비가 없어 정기적으로 거주할 적당한 장소가 없으므로 귀하와 함께 지내는 사람] 먼저 가장 나이가 어린 사람에 대해 묻겠습니다...

B10. 그 사람이 남자입니까 여자입니까?

- 1 남자
- 2 여자
- 8 모른다
- 9 헛갈린다

B20. 그 사람이 18세 이상입니까 미만입니까?

- 1 이상이다 (GOTO B30)
- 2 미만이다 (GOTO B21)
- 8 모른다 (GOTO B30)
- 9 헛갈린다 (GOTO B30)

B21. 그 사람[여자/남자]은 몇 살입니까?

- 1 5세 또는 그 미만 (GO TO B30)
- 2 6-12세
- 3 13-17세
- 8 모른다
- 9 헛갈린다

B22. 그 사람[여자/남자]이 학교에 다닙니까?

- 1 예
- 2 아니오
- 8 모른다
- 9 헛갈린다

B23. 그 사람[여자/남자]이 무숙자이기 때문에 상담, 주거 보조, 학교 통학 버스 등의 서비스를 받습니까?

- 1 예
- 2 아니오
- 8 모른다
- 9 헛갈린다

B30. 그 사람이 귀하의 친인척입니까?

- 1 예 (GOTO B35)
- 2 아니오 (GOTO B40)
- 8 모른다 (GOTO B40)
- 9 거부함 (GOTO B40)

B35. 이 사람은 귀하와 어떤 관계입니까?

\_\_\_\_\_ (250 CHAR TEXT)

88888 모른다

99999 헛갈린다

B40. 그 사람[여자/남자]이 안채 안에서 잡니까 밖에서 잡니까?

- 1 안채 안에서 (GOTO B41)
- 2 안채 밖에서 (GOTO B43)
- 8 모른다 (GOTO B50)
- 9 거부함 (GOTO B50)

B41. 그 사람[여자/남자]이 보통 집 안 어디에서 잡니까?

NOTE: Estimates not presented are zero

\* Measures of standard errors (SE) and relative standard errors (RSE) have been computed (as requested) for the estimated counts of hidden homeless in this table, but the sample size used to produce these estimates, and the rarity of hidden homelessness in the population makes these estimates of SE and RSE very unstable.

## **APPENDIX M**

### **Demographic Survey Instrument**

**2011 GREATER LOS ANGELES  
HOMELESS COUNT**  
***They Count. Will You?***

Thank you for agreeing to take this survey. To protect your privacy, we will not use your name in any of our reports. Your participation in this interview is voluntary and you may refuse to answer any question. You may also stop the interview at any time. First, I have just a few questions about your background to help us improve homeless services.

1. What are your initials? Please write your first, middle, and last initial.

--	--	--

2. What is your birth date? Please write the month, date, and year.

--	--	--	--

 / 

--	--	--

 / 

--	--	--	--

M M      D D      Y Y Y Y

3. Are you male or female?

- Male
- Female

4. Are you Hispanic or Latino?

- Yes
- No

5. What is your race? Choose all that apply.

- Black / African American
- White
- Asian / Pacific Islander
- American Indian / Alaskan Native
- Something else

↓  
What? \_\_\_\_\_

6. Have you served in the U.S. Armed Forces?

- Yes → **GO TO QUESTION 6c**
- No

- 6a. Were you a member of the National Guard or a Reservist?

- Yes
- No → **GO TO QUESTION 7**

- 6b. Was your unit ever put into Active Duty?

- Yes
- No → **GO TO QUESTION 7**

- 6c. What is your discharge status?

- Honorable
- Less than Honorable
- General
- Medical
- Dishonorable
- Still on Active Duty
- Other

↓  
What? \_\_\_\_\_

**7. Do you have any children under 18?**  
*Include step-children and children who are not your own*

- Yes
- No → **GO TO QUESTION 8**

**7a. Are you living with them now?**

- Yes
- No → **GO TO QUESTION 8**

**7b. Currently, how many of your children, under 18, live with you?**

- 0
- 1
- 2
- 3
- 4
- More than 4 → How many? \_\_\_\_\_

**7c. Of the children who live with you, how many are female?**

- 0
- 1
- 2
- 3
- 4
- More than 4 → How many? \_\_\_\_\_

**7d. Of the children who live with you, how many are male?**

- 0
- 1
- 2
- 3
- 4
- More than 4 → How many? \_\_\_\_\_

**8. What's the total amount of time you have been homeless over the course of your lifetime?**

- 7 days or less
- 8 – 29 days
- 1 – 3 months
- 4 – 5 months
- 6 – 11 months
- 1 – 5 years
- More than 5 years

**9. Including this time, how many separate times have you been homeless in the past three years?**

- 1 time
- 2 or 3 times
- 4 or more times

**10. Including this time, how many separate times have you been homeless in the past 12 months?**

- 1 time
- 2 or 3 times
- 4 or more times

**11. How long have you been homeless this time?**

- 7 days or less
- 8 – 29 days
- 1 – 3 months
- 4 – 5 months
- 6 – 11 months
- 1 – 5 years
- More than 5 years

**12. In the last 7 days, have you spent one or more nights outside of Los Angeles County?**

- Yes
- No

13. Over the last year, did you spend any nights outside, in a tent?

- Yes
- No → **GO TO QUESTION 14**

13a. Most recently, how many adults 18 or older stayed in the tent, including yourself?

- 1
- 2
- 3
- 4
- More than 4 → How many? \_\_\_\_\_

13b. Most recently, how many children under 18 stayed in the tent?

- 0 → **GO TO QUESTION 14**
- 1
- 2
- 3
- 4
- More than 4 → How many? \_\_\_\_\_

13c. How many of those adults did not have children with them when they stayed in the tent?

- 0
